ABSTRACT

LIHONG XIA. Essays on \(\lambda\)-quantile Dependent Convex Risk Measures.
(Under the direction of DR. MINGXIN XU)

We define a class of convex measures of risk whose values depend on the random variables only up to the \(\lambda\)-quantiles for some given constant \(\lambda \in (0, 1)\). For this class of convex risk measures, the assumption of Fatou property can be strengthened, and the robust representation theorem via convex duality method is provided. These results are specialized to the class of \(\lambda\)-quantile law invariant risk measures. We define the \(\lambda\)-quantile uniform preference (\(\lambda\)-quantile second order stochastic dominance) of two probability distribution measures and the \(\lambda\)-quantile dependent concave distortion and study their properties. The robust representation theorem of the \(\lambda\)-quantile dependent Weighted Value-at-Risk is proven via two different approaches: the \(\lambda\)-quantile uniform preference approach and the approach of maximizing the Choquet integral over the core of a \(\lambda\)-quantile dependent concave distortion. We demonstrate the two approaches in a classical example of Conditional Value-at-Risk and a new example of uniform \(\lambda\)-quantile dependent Weighted Value-at-Risk.
My deepest appreciation goes to my advisor Dr. Mingxin Xu for numerous conversations that clarified my thinking on the study of this topic and for her wise advice at critical times. Without her direction and guidance I would never have successfully pursued the Ph.D degree.

I am also grateful to Dr. Wihstutz, Dr. Zhu, and Dr. Hughen for serving as valuable members in my doctoral committee.

I thank my friends in the Charlotte area for their care, help, and encouragement through my Ph.D study.

Finally, I am particularly grateful to my husband Wenhong Su for being alway there for me with his unbounded love, tolerance, spiritual and material support.

This work is dedicated to my parents Xiaoguo Xia and Renjuan Cai.
# TABLE OF CONTENTS

INTRODUCTION 1

CHAPTER 1: REVIEW OF CONVEX MEASURE OF RISK AND THE ROBUST REPRESENTATION 9

1.1 The convex measure of risk and its acceptance set 9
1.2 The robust representation of the convex measure of risk 15
1.3 The law invariant risk measure and its robust representation 19
1.4 The Weighted Value-at-Risk and its representations 21

CHAPTER 2: λ-QUANTILE DEPENDENT CONVEX RISK MEASURE AND THE ROBUST REPRESENTATION 24

2.1 The λ-quantile dependent convex risk measure and the λ-quantile Fatou property 24
2.2 The robust representation of the λ-quantile dependent convex risk measure 26

CHAPTER 3: λ-QUANTILE LAW INVARIANT CONVEX RISK MEASURE 34

CHAPTER 4: ROBUST REPRESENTATION OF λ-QUANTILE DEPENDENT WEIGHTED VALUE-AT-RISK ρ(\mu,\lambda) 41

4.1 The relationship between the λ-quantile uniform preference and the core of λ-quantile dependent concave distortion 42
4.1.1 λ-quantile uniform preference of two probability distribution measures 42
4.1.2 Core of a λ-quantile dependent concave distortion 49
4.2 The robust representation of ρ(\mu,\lambda) 53
4.2.1 The robust representation of ρ(\mu,\lambda) via the λ-quantile uniform preference 54
4.2.2 The robust representation of ρ(\mu,\lambda) via the core of the λ-quantile concave distortion 59
4.3 Two examples 61
4.3.1 Conditional Value-at-Risk 61
4.3.2 Uniform λ-quantile dependent Weighted Value-at-Risk 62

REFERENCES 64
LIST OF NOTATIONS

\((\Omega, \mathcal{F}, P)\) : a probability space

\(\mathcal{X}\) : the collection of the random variables on \(\Omega\)

\(\mathcal{A}_\rho\) : the acceptance set of the risk measure \(\rho\)

\(L^0 := L^0(\Omega, \mathcal{F}, P)\) : the space of equivalent classes of all measurable functions on the probability space \((\Omega, \mathcal{F}, P)\)

\(L^\infty := L^\infty(\Omega, \mathcal{F}, P)\) : the space of equivalent classes of all essentially bounded functions on the probability space \((\Omega, \mathcal{F}, P)\)

\(L^p := L^p(\Omega, \mathcal{F}, P), 1 \leq p < \infty\) : the space of equivalent classes of measurable random variables such that for all \(X \in L^p\), \(\int |X|^p dP < \infty\)

\(ba := ba(\Omega, \mathcal{F}, P)\) : the space of all finitely additive measures \(\mu\) which are absolutely continuous to \(P\) and whose total variation is finite.

\(Q_\rho\) : the set of probability measures on \((\Omega, \mathcal{F}, P)\) such that \(Q \ll P\) and \(\frac{dQ}{dP} \in L^q\) with \(\frac{1}{p} + \frac{1}{q} = 1\) for \(1 \leq p \leq \infty\)

\(q_X(\lambda)\) : the \(\lambda\)-quantile of the random variable \(X\)

\(q^+_X(\lambda)\) : the upper \(\lambda\)-quantile of the random variable \(X\)

\(q^-_X(\lambda)\) : the lower \(\lambda\)-quantile of the random variable \(X\)

\(\sigma(L^\infty, L^1)\) : the weak* topology on \(L^\infty\)

\(X \sim Y\) : the random variables \(X\) and \(Y\) have the same probability distributions

\(\mu \gtrsim uni \nu\) : The probability measure \(\mu\) is uniformly preferred over the probability measure \(\nu\)

\(\mu \gtrsim uni(\lambda) \nu\) : The probability measure \(\mu\) is \(\lambda\)-quantile uniformly preferred over the probability measure \(\nu\)
INTRODUCTION

How to measure the riskiness of financial positions is an important yet complex topic for financial institutes such as banks and insurance companies as well as regulators. The financial crisis started in 2008 has shown us how critical risk measures are. Measuring risk, theoretically, involves how to define a proper measure to quantify the riskiness of a financial position and to study the properties of the measure; while practically, involves how to estimate and predict the selected measure using historic data. My research focuses on the first point. We define the class of "$\lambda$-quantile dependent" convex risk measures and study its properties.

According to Artzner, Delbaen, Eber and Heath (1999), the nature of a risk measure lies in the capital requirements that can be added to a financial position to make it acceptable from the point of view of an agent or a regulator. The paper of Artzner et al. (1999) is the mathematical foundation of studying the measure of risk, in which “a unified framework for the definition, analysis, construction and implementation" of the measure of risk was proposed and axioms of the class of the “coherent measures of risk" and its “robust representation” were given. In their framework, $\Omega$ denotes the possible outcomes of market scenarios, which is assumed to be finite. A random variable $X : \Omega \rightarrow \mathbb{R}$ indicates the “final net worth” of a position for each element of $\Omega$, and the collection of all these random variables is denoted by $\mathcal{X}$. A risk measure $\rho$ is then a mapping from $\mathcal{X}$ to the real line $\mathbb{R}$, $\rho : \mathcal{X} \rightarrow \mathbb{R}$. From the point of view of an agent or a regulator, a financial position is either “acceptable” or “unacceptable” with regard to its final net worth. The collection of all acceptable financial positions is called the “acceptance set” and denoted by $\mathcal{A}$. Obviously, $\mathcal{A} \subset \mathcal{X}$. Given a measure of risk $\rho$, its acceptance set $\mathcal{A}_\rho$ is $\mathcal{A}_\rho = \{X \in \mathcal{X} : \rho(X) \leq 0\}$. On the other hand, since a risk measure is the capital requirement to make a financial position acceptable, start from an acceptance set $\mathcal{A}$, a measure of risk $\rho$ can be recovered as $\rho(X) = \inf\{m \in \mathbb{R} \mid m + X \in \mathcal{A}\}$, for $X \in \mathcal{X}$. The coherent measure of risk is a special class of measures of risk. The coherent measure of risk $\rho$ possesses the properties (axioms) of monotonicity, translation invariance, subadditivity and positive homogeneity. Artzner
et al. showed that these axioms have correspondence to the axioms of the acceptance sets of the coherent risk measure, and for a coherent measure of risk $\rho$ in the current setting (i.e., finite $\Omega$), $\rho = \rho_{A^c}$. Artzner et al. (1999) provided a representation, also known as the robust representation, of the coherent measure of risk $\rho$: $\rho(X) = \sup_{Q \in \mathcal{Q}} \mathbb{E}_Q[-X]$, where $\mathcal{Q}$ is a family of probability measures on $\Omega$. Note that $\Omega$ is assumed to be finite.

Delbaen (2002) extended the coherent measure of risk to the general space $L^0 := L^0(\Omega, \mathcal{F}, P)$, the space of equivalent classes of all measurable functions on the probability space $(\Omega, \mathcal{F}, P)$, with a general set of $\Omega$. Since $\Omega$ can contain infinite number of elements, the random variables in $L^0$ are not anymore bounded. Thus, the coherent measure of risk $\rho : L^0 \to \mathbb{R} \cup \{\infty\}$ could take infinite value. Delbaen pointed out that the probability measure $P$ added to the space $(\Omega, \mathcal{F})$ is necessary to consider the probability space $L^0$, however, it is not really important which particular $P$ is added, since the robust representation of the coherent measure of risk indicates that only the set of probability measures that are equivalent to $P$ matters.

A more general class of measures of risk is the convex measure of risk. The law invariant measure of risk is a subclass of the convex measure of risk. In summary, there are three classes of risk measures that are precisely studied so far: the coherent measure of risk, the convex measures of risk, and the law invariant measure of risk.

**The coherent measure of risk:** As mentioned, this class of measures of risk was originally defined by Artzner et al. (1999) for finite market scenarios and was extended Delbaen (2002) to the general state space. A coherent measure of risk satisfies axioms of translation invariance, monotonicity, subadditivity and positive homogeneity. Artzner et al. (1999) proposed the robust representation using the expectations of the random variables. Delbaen (2002) showed that for a general state space $\Omega$, the robust representation of a coherent measure of risk exists under some condition. He proposed the equivalent conditions including the Fatou property which was first time defined for a measure of risk.

**The convex measure of risk:** It is a generalization of the coherent measure of risk in-
dependently made by Föllmer and Schied (2002) and Frittelli and Rosazza Gianin (2002). For a convex measure of risk, subadditivity and positive homogeneity are replaced by the convexity. For different probability spaces, the robust representation as well as equivalent conditions for the existence of the robust representation were proposed by Föllmer and Schied (2002), Frittelli and Rosazza Gianin (2002), Föllmer and Schied (2004), Biagini and Frittelli (2009), Kaina and Rüschendorf (2009).

The law invariant measure of risk: Kusuoka (2001) first studied those coherent measures of risk whose values depend on the random variables only through their probability distributions, and call them the “law invariant coherent risk measures”. He further showed that the law invariance coherent risk measure \( \rho \) defined on the space \( L^\infty := L^\infty(\Omega, \mathcal{F}, P) \), the equivalent classes of essentially bounded random variables, can be represented by the Weighted Value-at-Risk, if \( \rho \) has the Fatou property. The definition of the “law invariance” can be extended to the convex measure of risk, which was done by Föllmer and Schied (2004) and Frittelli and Rosazza Gianin (2005). Later, Jouini, Schachermayer and Touzi (2006) proved that all law invariant convex measures of risk on \( L^\infty \) already have the Fatou property.

In addition, as a particular subclass of the convex measure of risk, the Weighted Value-at-Risk is of great interest to researchers.

**The Weighted Value-at-Risk (WVaR):** This is a subclass of the convex measure of risk, it is coherent as well as law invariant. The WVaR includes the well-known Conditional Value-at-Risk (CVaR). It first appeared in Kusuoka (2001) as the one who represents the law invariant coherent measure of risk. Though Kusuoka did not give a particular name to it, he showed that on the space \( L^\infty \), the WVaR is a law invariant and comonotonic coherent risk measure and it has the Fatou property. Kusuoka also proposed a representation using the Choquet integral. Acerbi (2002) named this class of risk measures the “spectral measure of risk”. Föllmer and Schied (2004) call it the “concave distortion” and provided the robust representation using the second order stochastic dominance of a concave core. Cherny (2006) named this
class of risk measures the “Weighted Value-at-Risk” and extended it into the space \( L^0 \).

An important point on the study of the convex measure of risk (including the coherent measure of risk) is under what conditions the robust representation exists. If \( \Omega \) is finite, Artzner et al. (1999) showed that a measure of risk \( \rho \) is coherent if and only if there exists a family \( Q \) of probability measures on \( \Omega \) such that

\[
\rho(X) = \sup_{Q \in Q} E_Q[-X], \quad \text{for } X \in \mathcal{X}.
\] (1)

The representation (1) links the coherent measure of risk to the expectations of the negative financial positions, and the supremum in (1) shows the robustness of \( \rho \) in the sense that the more probability measures are included in the representation set \( Q \), the more conservative is the risk measure. The representation (1) is called the “robust representation” of a coherent measure of risk. When a general \( \Omega \) (i.e., \( \Omega \) may contain infinitely many elements) is considered, more conditions are needed for a coherent measure of risk to be representable. Delbaen (2002) proposed these conditions. For the coherent measure of risk \( \rho : L^\infty \to \mathbb{R} \), he defined the “Fatou property”: for any sequence of random variables \((X_n) \subset L^\infty\) such that \((X_n)\) is uniformly bounded by some constant \(C\), \(\rho\) has the Fatou property if \(\rho(X) \leq \liminf_{n \to \infty} \rho(X_n)\) whenever \(X_n \to X\) \(\mathbb{P}\)-a.s. for some \(X \in L^\infty\). Delbaen showed that the Fatou property is sufficient as well as necessary for the acceptance set \(A_{\rho}\) of \(\rho\) to be weak* closed. Then, the robust representation (1) exists due to the bipolar theorem. Moreover, Delbaen showed that the Fatou property is in fact equivalent to that \(\rho\) is continuous from above. Since the representation (1) is continuous from above, \(\rho\) has the Fatou property is equivalent to that \(\rho\) has the representation (1).

For the robust representation of a convex measure of risk \(\rho : L^\infty \to \mathbb{R}\), both Föllmer and Schied (2002) and Frittelli and Rosazza Gianin (2002) achieved the following representation:

\[
\rho(X) = \sup_{Q \in Q} (E_Q[-X] - \rho^*(Q)),
\] (2)
with $\rho^*$ a penalty function and $Q$ the representation set which can be identified. However, their approaches to show (2) are different: Föllmer and Schied used the approach similar to Delbaen (2002), while Frittelli and Rosazza Gianin (2002) used the Fenchel-Legendre duality.

To extend the robust representation (2) to the convex measure of risk defined on the functional space $L^p := L^p(\Omega, \mathcal{F}, P)$, $1 \leq p < \infty$, the functional space such that for any $X \in L^p$, $\int_{\mathbb{R}} |X|^p dP < \infty$, Biagini and Frittelli (2009) modified Delbaen’s Fatou property: for any sequence $(X_n) \subset L^p$ such that $(X_n)$ is dominated by some random variable $Y \in L^p$, a convex measure of risk $\rho : L^p \to \mathbb{R} \cup \{\infty\}$ has the Fatou property if $\rho(X) \leq \lim \inf \rho(X_n)$ whenever $X_n \to X$ $P$-a.s. for some $X \in L^p$. The difference of the two Fatou properties is the boundedness of $(X_n)$ required. In Delbaen’s definition, $(X_n)$ is bounded by some constant uniformly, while in Biagini and Frittelli’s definition, $(X_n)$ must be dominated by some random variable. Under the modified Fatou property, Biagini and Frittelli provided the robust representation of a convex and monotone functional defined on a locally convex Frechet lattice. Later on, Kaina and Rüschendorf (2009) specified Biagini and Frittelli’s results onto the convex measure of risk $\rho : L^p \to \mathbb{R} \cup \{\infty\}$.

When measuring risk, we are usually more concerned with downside risk than the upside profit for the portfolio. In fact, many convex risk measures we consider such as the Conditional Value-at-Risk (CVaR), the Weighted Value-at-Risk (WVaR), or non-convex risk measure such as Value-at-Risk (VaR), depend only on the lower quantiles of the financial positions up to some fixed significant level $\lambda \in (0, 1)$. We call this class of convex risk measures the “$\lambda$-quantile dependent” convex risk measure and study it from the following points:

The $\lambda$-quantile Fatou property: The $\lambda$-quantile dependent convex risk measure is a convex measure of risk $\rho : L^p \to \mathbb{R} \cup \{\infty\}$ whose value depends on the random variables only up to a given level $\lambda \in (0, 1)$. Since a $\lambda$-quantile dependent convex risk measure belongs to the class of the convex measures of risk, it is representable under the Fatou property defined by Biagini and Frittelli (2009). However, since
the risk measure depends on the random variable only up to the level $\lambda$, it is more natural to require the lower $\lambda$-quantiles of the sequence $(X_n)$ to be uniformly bounded above by some constant. Therefore, we define the $\lambda$-quantile Fatou property as the following: For a sequence of random variables $(X_n) \subset L^p$ such that their $\lambda$-quantiles are uniformly bounded by some real numbers, a convex measure of risk $\rho : L^p \to \mathbb{R} \cup \{\infty\}$ has the $\lambda$-quantile Fatou property if $\rho(X) \leq \lim \inf \rho(X_n)$ whenever $X_n \to X$ $\mathbb{P}$-a.s. for some $X \in L^p$. The boundedness condition we adopt in defining the $\lambda$-quantile Fatou property yield the lower semicontinuity for the $\lambda$-quantile dependent risk measure and its robust representation (2). When the risk measure is restricted to be $\lambda$-quantile dependent, the corresponding $\lambda$-quantile Fatou property turns out to be stronger in the sense that the boundedness on the quantile function can be more readily satisfied than the boundedness on the entire random variable, so the continuity property works for a larger class of sequences of random variables.

The $\lambda$-quantile law invariant risk measure: This is a subclass of the $\lambda$-quantile dependent convex risk measure. A $\lambda$-quantile law invariant risk measure is a convex measure of risk that depends only on the law of the random variables up to the given significance level $\lambda$. We propose a representation theorem for this class of risk measures.

The $\lambda$-quantile dependent WVaR: As an important subclass of the $\lambda$-quantile dependent convex risk measure, we define the $\lambda$-quantile dependent Weighted Value-at-Risk ($\lambda$-quantile dependent WVaR), denoted as $\rho_{\mu,\lambda}$. We first define the $\lambda$-quantile dependent Weighted Value-at-Risk for some fixed $\lambda \in (0, 1)$ as

$$
\rho_{\mu,\lambda}(X) = \int_{[0,\lambda]} CVaR_{\gamma}(X) \mu(d\gamma), \quad X \in L^p, \quad 1 \leq p \leq \infty,
$$

with $\mu$ a probability measure on $[0, \lambda]$ and $\mu(\{0\}) = 0$. $\rho_{\mu,\lambda}$ is coherent, law invariant and $\lambda$-quantile dependent. The $\lambda$-quantile dependent WVaR is law invariant and coherent. We prove the representation theorem for the $\lambda$-quantile dependent WVaR
by assuming that the probability space $\Omega$ is atomless. Similar to Carlier and Dana (2003), two approaches to the proof are adopted. The first one is to use the uniform preference of two probability distribution measures, also known as the second order stochastic dominance, which we extend the definition to the $\lambda$-quantile dependent case and study its properties for representation. The second approach hinges upon the relationship between cocomonotonic law invariant risk measures and Choquet integrals discovered by Schmeidler (1986). Showing the representation for the risk measure is reduced to finding the core of the Choquet integral. In the $\lambda$-quantile dependent WVaR case, we establish that

$$\rho_{\mu, \lambda}(X) = \int_0^{q_X(\lambda)} (\Psi(P(X < x)) - 1)dx + \int_{-\infty}^0 \Psi(P(X < x))dx,$$

where $\Psi$ is a $\lambda$-quantile dependent concave distortion. We verify that the above Choquet integral is the maximum of the expectation of $-X$ over the probability measures in the core of $\Psi(P)$. As an example, we give the robust representation of the Conditional Value-at-Risk CVaR$\lambda$ using these two approaches and check that the representation sets achieved from these different methods are indeed the same, and they also coincide with the well-known result obtained from Neyman-Pearson Lemma by Föllmer and Schied (2004). We also show the robust representation in a new example which we call the uniform $\lambda$-quantile dependent Weighted Value-at-Risk.

This thesis is organized in the following way:

In Chapter 1, we review the definition of the convex measure of risk and the theorem of the robust representation. As a subclass of the convex measure of risk, we also review the law invariant measure of risk and its representation.

In Chapter 2, we define the class of $\lambda$-quantile dependent convex risk measures. The $\lambda$-quantile Fatou property is defined to show the representation theorem.

In Chapter 3, we define the class of $\lambda$-quantile law invariant risk measure and propose a representation similar to the law invariant measure of risk.
In Chapter 4, we first define the class of \( \lambda \)-quantile dependent WVaR. We then define the \( \lambda \)-quantile uniform preference of two probability distribution measures and study its properties. The robust representation of the \( \lambda \)-quantile dependent WVaR is proposed via the \( \lambda \)-quantile uniform preference and the core of the concave distortion respectively. As an example, we give the robust representation of the Conditional Value-at-Risk CVaR_{\lambda} using the above two approaches and check that this robust representation coincides to the well known one. Finally, we give the robust representation of the uniform \( \lambda \)-quantile dependent WVaR.
CHAPTER 1: REVIEW OF CONVEX MEASURE OF RISK AND THE ROBUST REPRESENTATION

Artzner et al. (1999) first defined the coherent measure of risk \( \rho \) for a finite set of market scenarios both through adding axioms on \( \rho \) and through adding axioms on the acceptance set of \( \rho \). A more generalized class of risk measures is the convex measure of risk. In this chapter, we review the axiomatic definition of the convex measure of risk and the coherent measure of risk, the relation between the axioms and axioms on the acceptance set, and the robust representation of the convex measure of risk and the coherent measure of risk.

1.1 The convex measure of risk and its acceptance set

Let \( \Omega \) be a fixed set of scenarios, finite or infinite. The discounted net worth of a financial position at the end of trading period is modeled by a random variable \( X : \Omega \rightarrow \mathbb{R} \). The collection of all discounted net worth of the financial positions is denoted by \( \mathcal{X} \).

**Definition 1.1.** (measure of risk) Let \( \rho : \mathcal{X} \rightarrow \mathbb{R} \cup \{\infty\} \) be a mapping.

1. \( \rho \) is a monetary measure of risk, if it satisfies the following axioms:
   - Monotonicity: For any \( X, Y \in \mathcal{X} \) such that \( X \leq Y \), \( \rho(X) \geq \rho(Y) \).
   - Cash invariance: For any \( X \in \mathcal{X} \) and any \( m \in \mathbb{R} \), \( \rho(X + m) = \rho(X) - m \).

2. \( \rho \) is a convex measure of risk, if it is a monetary measure of risk and satisfies:
   - Convexity: For any \( X, Y \in \mathcal{X} \) and any \( \lambda \in [0, 1] \),
     \[ \rho(\lambda X + (1 - \lambda)Y) \leq \lambda \rho(X) + (1 - \lambda) \rho(Y). \]

3. \( \rho \) is a coherent measure of risk, if it is a monetary measure of risk and satisfies:
   - Positive Homogeneity: For \( \alpha \geq 0 \), \( \rho(\alpha X) = \alpha \rho(X) \), for any \( X \in \mathcal{X} \).
• Subadditivity: For any $X, Y \in \mathcal{X}$, $\rho(X + Y) \leq \rho(X) + \rho(Y)$.

Remark. We have the following remarks on Definition 1.1:

1. The definition of the convex measure of risk was proposed independently by Föllmer and Schied (2002) and Frittelli and Rosazza Gianin (2002), where $\rho$ was assumed to be real-valued. However, when a random variable $X \in \mathcal{X}$ is not bounded, we can not eliminate the possibility that $\rho$ takes infinite value. For example, for $\mathcal{X} := L^0(\Omega, \mathcal{F}, P)$ with $(\Omega, \mathcal{F}, P)$ an atomless probability space, Delbaen (2002) showed that there was no finite-valued coherent measure of risk since the functional space $L^0$ is not locally convex. Thus, we require $\rho$ is a mapping from $\mathcal{X}$ to the extended real line $\mathbb{R} \cup \{\infty\}$.

2. Artzner et al. (1999) interpreted the axiom of subadditivity of the coherent measure of risk as “a merger does not create extra risk”, which means that the risk of the aggregate position is bounded by the sum of the individual risk limits.

3. For the convex measure of risk, the axiom of convexity can be explained in a similar way: “diversification should not increase risks”. More precisely, the risk of a diversified position $\lambda X + (1 - \lambda)Y$ is not larger than the weighted sum of the positions $X$ and $Y$. This interpretation can be found in Föllmer and Schied (2002) and Frittelli and Rosazza Gianin (2002).

Remark. We make some remarks on the set $\mathcal{X}$. In the first paper on the coherent measure of risk by Artzner et al. (1999), the set of market scenarios $\Omega$ was assumed to be finite. Thus, all elements in $\mathcal{X}$ are naturally uniformly bounded. Delbaen (2002) considered a general set $\Omega$ which contains finite or infinite number of scenarios. He argued that it was necessary to consider a fixed probability space $(\Omega, \mathcal{F}, P)$. He then chose $\mathcal{X} := L^0 := L^0(\Omega, \mathcal{F}, P)$, the space of all equivalence classes of measurable functions on $(\Omega, \mathcal{F}, P)$, and considered the coherent measure of risk on $L^0$. Delbaen (2002) pointed out that there was actually no finite-valued coherent measure of risk $\rho$ on $L^0$ since the space $L^0$ is not locally convex. Therefore, he defined the coherent measure of risk $\rho$ as a mapping from $L^0$ to $\mathbb{R} \cup \{\infty\}$.
which satisfied axioms of the coherent measure of risk proposed by Artzner et al. (1999).

If we choose locally convex set such as \( \mathcal{X} = L^\infty(\Omega, \mathcal{F}, \mathbb{P}) \), the space of equivalence classes of essentially bounded random variables, or \( \mathcal{X} = L^p(\Omega, \mathcal{F}, \mathbb{P}) \), \( 1 \leq p < \infty \), the space of equivalence classes of integrable random variables, it is much more convenient to define and study the coherent measure of risk. When defining the convex measure of risk, Föllmer and Schied (2002) chose \( \mathcal{X} = L^\infty \) and considered \( \rho : \mathcal{X} \to \mathbb{R} \) as a real-valued mapping. Frettelli and Rosazza Gianin (2002) assumed the set \( \mathcal{X} \) to be an ordered locally convex topological vector space, where \( L^p := L^p(\Omega, \mathcal{F}, \mathbb{P}), 1 \leq p \leq \infty \), are included. Kaina and Rüschendorf (2009) studied the convex measure of risk defined on \( L^p \) space with \( 1 \leq p \leq \infty \), i.e., \( \rho : L^p(\Omega, \mathcal{F}, \mathbb{P}) \to \mathbb{R} \cup \{\infty\} \).

**Definition 1.2. (acceptance set)** The acceptance set \( A_\rho \) of a monetary measure of risk \( \rho : \mathcal{X} \to \mathbb{R} \cup \{\infty\} \) is defined as

\[
A_\rho := \{ X \in \mathcal{X} : \rho(X) \leq 0 \}.
\] (1.1)

Definition 1.2 means that a financial position is acceptable if no additional capital is required to make the risk to be non-positive. Artzner et al. (1999) demonstrated that there was certain correspondence between the axioms on the acceptance set and the axioms on the coherent measure of risk. Similar correspondence exists for the convex measure of risk, as Föllmer and Schied (2004) showed. Before we give the summary of the relations between the convex measure of risk and its acceptance set, we first recall that a monetary measure of risk \( \rho : \mathcal{X} \to \mathbb{R} \cup \{\infty\} \) is proper, if \( \rho(X) < \infty \) for some \( X \in \mathcal{X} \). For a proper monetary measure of risk \( \rho \) with acceptance set \( A_\rho \), we have the following:

1. \( A_\rho \) is non-empty.

2. \( A_\rho \) is monotone: if \( X \in A_\rho \) and \( Y \in \mathcal{X} \) such that \( Y \geq X \), then \( Y \in A_\rho \).

3. \( \rho \) is convex if and only if \( A_\rho \) is convex.

4. \( \rho \) is coherent if and only if \( A_\rho \) is a convex cone, i.e., \( A_\rho \) is convex and \( A_\rho \) is a cone.

Recall that a set \( S \) is a cone if \( s \in S \) implies \( \alpha s \in S \) for every \( \alpha \geq 0 \).
5. $\rho$ can be recovered from $A_{\rho}$:

$$
\rho(X) = \begin{cases} 
\infty & \text{if } m + X \notin A_{\rho}, \forall m \in \mathbb{R}, \\
\inf \{ m \in \mathbb{R} : m + X \in A_{\rho} \} & \text{otherwise}. 
\end{cases}
$$

Conversely, start from a non-empty set $A \subset \mathcal{X}$ such that $A$ is convex and monotone, and

$$
\inf \{ m \in \mathbb{R} : m + X \in A \} > -\infty, \quad \text{for all } X \in \mathcal{X},
$$

we can define a convex measure of risk

$$
\rho_A(X) := \inf \{ m \in \mathbb{R} : m + X \in A \}, \quad \text{for } X \in \mathcal{X}. \quad (1.2)
$$

In addition, we have:

1. If $A$ is a cone, then $\rho_A$ is a coherent measure of risk.

2. $A \subset A_{\rho_A}$.

3. $A = A_{\rho_A}$ if for any $X \in A$ and any $Y \in \mathcal{X}$, the set $\{ \lambda \in [0, 1] : \lambda X + (1 - \lambda)Y \in A \}$ is closed in $[0, 1]$.

As examples of risk measures, we look at the Value-at-Risk, the Conditional Value-at-Risk, and the Weighted Value-at-Risk. All these risk measures are quantile-dependent. The Value-at-Risk at a fixed level $\lambda \in [0, 1]$, denoted by $VaR_\lambda$, is the negative $\lambda$-quantile of the random variables. In practice, $VaR$ is widely used, but it is not a convex measure of risk, i.e., it may penalize diversification. The Conditional Value-at-Risk at some fixed level $\lambda$, denoted by $CVaR_\lambda$, and also known as the Average Value-at-Risk or the expected shortfall, takes the average of the $VaR$ up to the level $\lambda$ equally weighted. Unlike the Value-at-Risk, the $CVaR$ is a coherent measure of risk. The Weighted Value-at-Risk $WVaR$ averages the $VaR_\lambda$ over the interval $(0, 1]$ with the weights given by a probability measure $\mu$ on $(0, 1]$. We list these examples in Example 1.1.
Let us first recall some quantile-related definitions. Given a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and a fixed number $\lambda \in (0, 1)$, a $\lambda$-quantile of a random variable $X$ is any real number $q$ such that

$$\mathbb{P}(X \leq q) \geq \lambda \quad \text{and} \quad \mathbb{P}(X < q) \leq \lambda. \quad (1.3)$$

We use $q_X(\lambda)$ to denote a $\lambda$-quantile of $X$. Note that $q_X(\lambda)$ may be not unique. The lower- and upper $\lambda$-quantile of the random variable $X$ are denoted by $q_X^{-}(\lambda)$ and $q_X^{+}(\lambda)$ respectively, and they are defined by

$$q_X^{-}(\lambda) := \sup\{x : \mathbb{P}(X < x) < \lambda\} = \inf\{x : \mathbb{P}(X \leq x) \leq \lambda\},$$

$$q_X^{+}(\lambda) := \inf\{x : \mathbb{P}(X \leq x) > \lambda\} = \sup\{x : \mathbb{P}(X < x) \leq \lambda\}. \quad (1.4)$$

Note that the $\lambda$-quantiles as well as the upper- and lower $\lambda$-quantiles are well defined (real-valued) for all $\lambda \in [0, 1]$ if the random variable $X$ is bounded. If $X$ is not bounded, we may use the notation $q_X(0) = q_X^{-}(0) := -\infty$ and $q_X(1) = q_X^{+}(1) := \infty$.

**Example 1.1. (VaR, CVaR, and WVaR)**

In the following examples, we suppose $X = L^p$ with $1 \leq p \leq \infty$. Moreover, we assume $\lambda \in [0, 1]$ to be a fixed number.

- The Value-at-Risk $VaR_\lambda(X)$ of a financial position $X$ has the following definition:

  $$VaR_\lambda(X) := -q_X^{+}(\lambda) = q_X^{-}(1 - \lambda). \quad (1.5)$$

$VaR_\lambda(X)$ controls the probability of a loss, but does not control the size of a loss if it occurs. $VaR_\lambda(X)$ is a monetary measure of risk, however, it is not convex.

If $X = L^\infty$, $VaR_\lambda(X)$ is finite for all $\lambda \in [0, 1]$ and all $X \in L^\infty$, where we define

$$VaR_0(X) := -\text{ess inf}X = \inf\{m \in \mathbb{R} : \mathbb{P}(X + m < 0) = 0\},$$

$$VaR_1(X) := -\text{ess sup}X = \inf\{m \in \mathbb{R} : \mathbb{P}(X - m > 0) = 0\}.$$  

When $X = L^p$, $1 \leq p < \infty$, $VaR_0(X)$ may be $\infty$ and $VaR_1(X)$ may be $-\infty$. 

In this case, the measure of risk \( \text{VaR}_\lambda \) can be defined as a mapping from \( L^p \) to \( \mathbb{R} \cup \{-\infty\} \cup \{\infty\} \).

- **The Conditional Value-at-Risk at level \( \lambda \)** is defined as

\[
\text{CVaR}_\gamma(X) := -\frac{1}{\lambda} \int_0^\lambda \text{VaR}_\gamma(X) d\gamma = -\frac{1}{\lambda} \int_0^\lambda q_X(t) dt. \tag{1.6}
\]

\( \text{CVaR}_\gamma(X) \) averages the Value-at-Risk of \( X \) up to the level \( \lambda \) with equal weights. It is a coherent measure of risk.

Note that if \( X = L^\infty \), \( \text{CVaR}_\lambda \) is finite for all \( X \in L^\infty \) with \( \text{CVaR}_0(X) := -\text{ess inf} X \) and \( \text{CVaR}_1(X) := -\text{ess sup} X \).

For an unbounded \( X \in L^p \), \( 1 \leq p < \infty \), \( \text{CVaR}_0(X) \) will be \( \infty \). However, \( \text{CVaR}_1(X) = \int_0^1 q_X(t) dt = \mathbb{E}[-X] < \infty \).

- **Let \( \mu \) be a probability measure on \((0, 1]\).** The **Weighted Value-at-Risk** of a financial position \( X \), denoted by \( \rho_\mu(X) \), has the definition

\[
\rho_\mu(X) := \int_{(0,1]} \text{CVaR}_\gamma(X) \mu(d\gamma).
\]

\( \rho_\mu \) is a coherent measure of risk.

Note that the interval \((0, 1]\) is half-opened. Alternatively, we can assume \( \mu \) is a probability measure on the closed interval \([0, 1]\) satisfying \( \mu(\{0\}) = 0 \). If this were not the case, it may occur \( \infty - \infty \) in the integral for an unbounded \( X \). We will discuss more details on the Weighted Value-at-Risk in section 1.4.
1.2 The robust representation of the convex measure of risk

In this section, \((\Omega, \mathcal{F}, P)\) is a fixed probability space. For \(1 \leq p \leq \infty\), the \(L^p\) spaces are Banach spaces whose norms are defined by

\[
\|X\|_p := \begin{cases} 
(f \mid X|p\,dP)^{1/p} & \text{for } 1 \leq p < \infty, \\
\text{esssup}(X) := \inf \{x : P(|X| > x) = 0\} & \text{for } p = \infty.
\end{cases}
\]

The \(L^p\) spaces are locally convex spaces. For \(1 \leq p < \infty\), the dual space of \((L^p, \| \cdot \|_p)\) is the space \((L^q, \| \cdot \|_q)\) with \(q\) some real number satisfying \(\frac{1}{p} + \frac{1}{q} = 1\); If \(p = \infty\), the dual space of \((L^\infty, \| \cdot \|_\infty)\) is the space \(ba := ba(\Omega, \mathcal{F}, P)\), the space of all finitely additive measures \(\mu\) which are absolutely continuous to \(P\) and whose total variation is finite. The space \(ba\) contains not only probability measures, but also the finitely additive measures.

The weak* topology on \(L^\infty\), denoted as \(\sigma(L^\infty, L^1)\), is the coarsest topology on \(L^\infty\) to make every linear functional \(\ell : L^\infty \to L^1\) be continuous. Endowed with the weak* topology, the dual space of \((L^\infty, \sigma(L^\infty, L^1))\) is \(L^1\). We refer the book of Dunford and Schwartz (1964) for more details on the \(L^p\) spaces and their dual spaces.

We define the following set of probability measures:

\[
Q_p := \left\{ Q \text{ probability measure on } (\Omega, \mathcal{F}, P) : Q \ll P \text{ and } \frac{dQ}{dP} \in L^q \right\}, \quad (1.7)
\]

where \(L^q\) is the dual space of \(L^p\) for \(1 \leq p < \infty\), and for \(p = \infty\), we use \(L^q\) for convenience to denote the space \(L^1\), the dual space of \((L^\infty, \sigma(L^\infty, L^1))\).

For the discussion of the robust representation of the convex measure of risk, we first recall the definition of a lower semicontinuous function.

**Definition 1.3.** A function \(f : E \to [-\infty, \infty]\) on a topological space \(E\) is lower semicontinuous if the set \(\{x \in E : f(x) \leq \alpha\}\) is closed for all \(\alpha \in \mathbb{R}\).

We refer the book of Aliprantis and Border (2006) for more related topics on the lower semicontinuity.

We also recall the following definition and theorem from Föllmer and Schied (2004).
Definition 1.4. (Fenchel-Legendre transform) Let $E$ be a topological space and $E'$ be its dual space. The Fenchel-Legendre transform of a function $f : E \to \mathbb{R} \cup \{\infty\}$ is the function $f^* : E' \to \mathbb{R} \cup \{\infty\}$ defined by

$$f^*(\ell) := \sup_{x \in E} (\ell(x) - f(x)), \quad (1.8)$$

For the following theorem, we recall that a function $f : E \to \mathbb{R} \cup \{\infty\}$ is proper, if there is some $x \in E$ such that $f(x) < \infty$.

**Theorem 1.2.** Let $f$ be a proper convex function on a locally convex topological space $E$. If $f$ is lower semicontinuous with respect to the weak topology $\sigma(E, E')$, then $f = f^{**}$, where $f^{**}$ is the Fenchel-Legendre transform of $f^*$.

**Remark.** In Theorem 1.2, the topological space $E$ is required to be locally convex. A topological space $E$ is locally convex if has a base of convex sets. By this definition, the functional spaces $L^p$, $1 \leq p \leq \infty$, are locally convex, but the space $L^0$ is not locally convex if the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ is atomless.

For a convex measure of risk $\rho$ defined on the space $L^\infty$, Föllmer and Schied (2002) and Frittelli and Rosazza Gianin (2002) showed the following theorem:

**Theorem 1.3.** Suppose $\rho : L^\infty \to \mathbb{R}$ is a convex measure of risk. Then the following statements are equivalent:

1. $\rho$ is lower semicontinuous with respect to the weak* topology $\sigma(L^\infty, L^1)$.

2. $\rho$ admits the following robust representation:

$$\rho(X) = \sup_{Q \in \mathcal{Q}_1} (\mathbb{E}_Q[-X] - \rho^*(Q)), \quad \text{for all } X \in L^\infty, \quad (1.9)$$

where $\rho^*(Q) := \sup_{X \in L^\infty} (\mathbb{E}_Q[-X] - \rho(X))$ is the Fenchel-Legendre transform of $\rho$.

3. $\rho$ is continuous from above: If $X_n \searrow X$ $\mathbb{P}$-a.s., then $\rho(X_n) \nearrow \rho(X)$. 
4. \( \rho \) has the Fatou property: For any bounded sequence \((X_n)\) which converges \( \mathbb{P}\)-a.s. to some \( X \),

\[
\rho(X) \leq \liminf_{n \to \infty} \rho(X_n).
\]

For the convex measure of risk defined on \( L^p \), \( 1 \leq p < \infty \), Kaina and Rüschendorf showed the following theorem by using the extended Namioka-Klee theorem proven by Biagina and Frettelli (2009):

**Theorem 1.4.** Suppose \( \rho : L^p \to \mathbb{R} \cup \{\infty\}, 1 \leq p < \infty \), is a proper convex measure of risk. Then the following statements are equivalent:

1. \( \rho \) is lower semicontinuous with respect to the weak topology \( \sigma(L^p, L^q) \).

2. \( \rho \) has the following robust representation:

\[
\rho(X) = \sup_{Q \in \mathcal{Q}_p} (\mathbb{E}_Q[-X] - \rho^*(Q)), \quad \text{for all } X \in L^p, \quad (1.10)
\]

where \( \rho^*(Q) := \sup_{X \in L^p}(\mathbb{E}_Q[-X] - \rho(X)) \) is the Fenchel-Legendre transform of \( \rho \).

3. \( \rho \) is continuous from above: If \( X_n \searrow X \mathbb{P}\)-a.s., then \( \rho(X_n) \nearrow \rho(X) \).

4. \( \rho \) has the Fatou property: For any sequence \((X_n)\) such that for some \( Y \in L^p, |X_n| \leq Y \) \( \mathbb{P}\)-a.s., if \( X_n \) converges to \( X \mathbb{P}\)-a.s. for some \( X \in L^p \), then

\[
\rho(X) \leq \liminf_{n \to \infty} \rho(X_n).
\]

**Remark.**

1. The main difference of Theorem 1.3 and Theorem 1.4 is the definition of the Fatou property. As already mentioned in the Introduction section, random variables in \( L^\infty \) are essentially bounded, so sequences \((X_n) \subset L^\infty \) uniformly bounded by a constant are considered to define the Fatou property, as what Artzner et al.(1999) did. However, random variables in \( L^p \) are most likely not essential bounded when
\( p \neq \infty \), to define the Fatou property, Biagini and Frittelli (2009) require the sequence \((X_n) \subset L^p\) to be dominated by some random variable. This dominance allows us to use the Dominated Convergence Theorem when prove the Theorem.

2. A similar version to Theorem 1.3 for the coherent measure of risk was shown by Artzner et al. (1999). Since the coherent measure of risk is a subclass of the convex measure of risk, Theorem 1.3 can be applied to the coherent measure of risk. In particular, Föllmer and Schied (2002) showed that if a coherent measure of risk \( \rho : L^\infty \to \mathbb{R} \) can be represented by (1.9), then either \( \rho^*(Q) = 0 \) or \( \rho^*(Q) = \infty \) for each \( Q \in Q_1 \). Therefore, there must be some set \( Q \subset Q_1 \) such that the coherent measure of risk \( \rho \) can be represented as

\[
\rho(X) = \sup_{Q \in Q} \mathbb{E}_Q[-X], \quad \text{for } X \in L^\infty. \tag{1.11}
\]

This representation coincides to the one proposed by Artzner et al. (1999). Moreover, as shown by Kaina and Rüschendorf (2009), these results remain true if the coherent measure of risk is defined on the \( L^p \) space.

3. The equivalence of statement 1 and statement 2 in Theorem 1.3 and Theorem 1.4 is a direct consequence of Theorem 1.2, where \( \rho^* \) is the Fenchel-Legendre transform of \( \rho \). This approach of the proof was first stated by Frittelli and Rosazza Gianin (2002). When Föllmer and Schied (2002) proved Theorem 1.3, they used the Hahn-Banach theorem. Föllmer and Schied called the function \( \rho^* \) the “penalty function” and showed an alternative form of \( \rho^* \), namely

\[
\rho^*(Q) = \alpha_{\min}(Q) := \sup_{X \in A_\rho} \mathbb{E}_Q[-X], \quad \text{for } Q \in Q_1.
\]

Föllmer and Schied (2002) demonstrated that if \( \alpha(Q) \) is a penalty function, then it must be true that \( \alpha(Q) \geq \alpha_{\min}(Q) \) for all \( Q \in Q_1 \). This means that \( \alpha_{\min}(Q) \) is the minimal penalty function of \( \rho \).
1.3 The law invariant risk measure and its robust representation

Throughout this section, we consider the real-valued monetary measure of risk \( \rho : L^\infty \to \mathbb{R} \) defined on the space \( L^\infty \). We further assume that the probability space \( (\Omega, \mathcal{F}, P) \) is atomless in the sense of the following definition:

**Definition 1.5. (atomless probability space)** Let \( (\Omega, \mathcal{F}, P) \) be a probability space. An atom of the probability measure \( P \) is some set \( A \in \mathcal{F} \) such that \( P(A) > 0 \) and for any \( B \in \mathcal{F} \) and \( B \subset A \), either \( P(B) = 0 \) or \( P(B) = P(A) \). A probability space \( (\Omega, \mathcal{F}, P) \) is atomless if it contains no atoms.

The study of the law invariant risk measure was mainly contributed by Kusuoka (2001), where he defined the law invariant risk measure and proposed the robust representation for the class of the law invariant coherent measure of risk. The following definition is due to Kusuoka (2001).

**Definition 1.6. (law invariant risk measure)** A monetary measure of risk \( \rho : L^\infty \to \mathbb{R} \) is law invariant, if \( \rho(X) = \rho(Y) \) whenever \( X \) and \( Y \) have the same probability distribution under \( P \).

Let \( \rho : L^\infty \to \mathbb{R} \) be a convex measure of risk which is law invariant. If \( \rho \) has the Fatou property, then Theorem 1.3 ensures that \( \rho \) admits the robust representation (1.9). In addition, the law invariance property insures the following representation:

**Theorem 1.5.** Let \( \rho : L^\infty \to \mathbb{R} \) be a convex measure of risk that has the Fatou property formulated in Theorem 1.3. Then \( \rho \) is law invariant if and only if it can be represented as

\[
\rho(X) = \sup_{Q \in \mathcal{Q}_1} \left( \int_0^1 q_X(t)q_{-\varphi_Q(t)}(t)dt - \rho^*(Q) \right),
\]

where \( \varphi_Q := \frac{dQ}{dP} \), and

\[
\rho^*(Q) = \sup_{X \in L^1_\mu} \left( \int_0^1 q_X(t)q_{-\varphi_Q(t)}(t)dt - \rho(X) \right)
= \sup_{X \in \mathcal{A}_\mu} \int_0^1 q_X(t)q_{-\varphi_Q(t)}dt,
\]
where we recall the set \( Q_1 = \{ Q \text{ probability measure on } (\Omega, \mathcal{F}, P) : Q \ll P, \frac{dQ}{dP} \in L^1 \} \), and \( \mathcal{A}_\rho \) is the acceptance set of \( \rho \).

Theorem 1.5 can be found as Theorem 4.54 of Föllmer and Schied (2004), it generalizes Lemma 10 of Kusuoka (2001) for the coherent measure of risk defined on \( L^\infty \). (1.12) and (1.13) reflects the “law invariance” of \( \rho \), namely, \( \rho \) depends on the random variable \( X \) and the Radon Nikodým derivatives \( \frac{dQ}{dP} \) only through their laws.

Remark. In Theorem 1.5, the Fatou property is a sufficient and necessary condition which leads \( \rho \) to have the representation (1.12). For a law invariant convex measure of risk \( \rho : L^\infty \to \mathbb{R} \) defined on \( L^\infty \), Jouini et al. (2006) showed that \( \rho \) has automatically the Fatou property. Therefore, in Theorem 1.5 we can eliminate the condition that \( \rho \) has the Fatou property \( \rho \), and the conclusions remain true.

For a law invariant coherent risk measure defined on \( L^\infty \), Kusuoka (2001) proposed another representation by the Weighted Value-at-Risk \( \rho_\mu \) introduced in section 1.1:

\[
\rho_\mu(X) = \int_{(0,1]} CVaR_\gamma(X) \mu(\gamma).
\]

with \( \mu \) a probability measure on \( (0,1] \). Föllmer and Schied (2004) generalized this representation for the convex measure of risk \( \rho : L^\infty \to \mathbb{R} \). The following theorem is quoted from Theorem 4.57 of Föllmer and Schid (2004).

**Theorem 1.6.** A convex measure of risk \( \rho : L^\infty \to \mathbb{R} \) is law invariant if and only if \( \rho \) has the following representation:

\[
\rho(X) = \sup_{\mu \in \mathcal{M}_1((0,1])} \left( \int_{(0,1]} CVaR_\gamma(X) \mu(\gamma) - \beta_{\min}(\mu) \right),
\]

where \( \mathcal{M}_1((0,1]) \) indicates the set of all probability measures on \( (0,1] \), and

\[
\beta_{\min} = \sup_{X \in \mathcal{A}_\rho} \int_{(0,1]} CVaR_\gamma(X) \mu(\gamma).
\]

In particular, \( \rho \) is law invariant and coherent if and only if there is some set of probability
measures on \((0, 1]\), denoted by \(\mathcal{M}_0((0, 1])\), such that

\[
\rho(X) = \sup_{\mu \in \mathcal{M}_0((0, 1])} \int_{[0,1]} CVaR_\gamma(X) \mu(d\gamma).
\]

The proof of the theorem can be found in Kusuoka (2001) for the coherent case and in Föllmer and Schied (2004) for the convex case. Note that we do not need to assume \(\rho\) has the Fatou property since it is implied by the law invariance of \(\rho\). For the Weighted Value-at-Risk \(\rho_\mu\), we will take a closer look in the next section.

1.4 The Weighted Value-at-Risk and its representations

In this section, we assume that the probability space \((\Omega, \mathcal{F}, P)\) is atomless.

The Weighted Value-at-Risk \(\rho_\mu : L^\infty \to \mathbb{R}\) is defined on the functional space \(L^\infty\) and has the form of

\[
\rho_\mu(X) := \int_{[0,1]} CVaR_\gamma(X) \mu(d\gamma), \quad \text{for } X \in L^\infty, \tag{1.14}
\]

where \(\mu\) is a probability measure on \([0, 1]\) and \(CVaR_\gamma\) is defined by (1.6): \(CVaR_\gamma(X) = -\frac{1}{\gamma} \int_0^\gamma q_X(t) dt\), for \(\gamma \in [0, 1]\) and \(X \in L^\infty\). In particular, \(CVaR_0(X) := -\lim \inf X\) and \(CVaR_1(X) := -\lim \sup X\). The Weighted Value-at-Risk \(\rho_\mu\) is a coherent measure of risk.

Substituting \(CVaR_\gamma(X)\) into (1.14) and applying the Fubini’s Theorem, we yield

\[
\rho_\mu(X) = \mu(\{0\}) CVaR_0(X) + \int_{[0,1]} -\frac{1}{\gamma} \int_0^\gamma q_X(t) dt \mu(d\gamma)
\]

\[
= \mu(\{0\}) CVaR_0(X) - \int_{[0,1]} q_X(t) \int_{(t,1]} \frac{1}{\gamma} \mu(d\gamma) dt.
\]

Define

\[
\phi(t) := \int_{(t,1]} \frac{1}{\gamma} \mu(d\gamma), \quad \text{for } 0 < t < 1, \tag{1.15}
\]

then we obtain an alternative form for \(\rho_\mu\):

\[
\rho_\mu(X) = \mu(\{0\}) CVaR_0(X) - \int_{[0,1]} q_X(t) \phi(t) dt. \tag{1.16}
\]
As pointed out by Föllmer and Schied (2004), equation (1.15) defines a one-to-one correspondence between the probability measures $\mu$ on $(0, 1]$ and the increasing concave functions $\Psi : [0, 1] \rightarrow [0, 1]$, and the function $\Psi$ satisfies $\Psi'(t+) = \phi(t)$, $\Psi(0) = 0$, $\Psi(0+) = \mu(0)$, $\Psi(1) = 1$.

(1.16) is a slightly modified version of Kusuoka (2001). In addition, Föllmer and Schied (2004) showed the following equivalent form of $\rho_{\mu}$:

$$
\rho_{\mu}(X) = \int_{-\infty}^{0} (\Psi(P(X > x)) - 1) dx + \int_{0}^{\infty} \Psi(P(X > x)) dx,
$$

for $X \in L^\infty$. (1.17)

The right hand side of (1.17) is called the Choquet integral. More precisely, we have the following definition:

**Definition 1.7. (Choquet integral)** Let $c : \mathcal{F} \rightarrow [0, 1]$ be any set function which is normalized and monotone. The Choquet integral of a bounded measurable function $X$ on $(\Omega, \mathcal{F})$ with respect to $c$ is defined as

$$
\int X dc := \int_{-\infty}^{0} (c(X > x) - 1) dx + \int_{0}^{\infty} c(X > x) dx.
$$

(1.18)

Originally, the Choquet integral $\int_{\Omega} X dc$ was first defined by Choquet (1954) for a bounded, non-negative and $\mathcal{F}$-measurable function $X : \Omega \rightarrow \mathbb{R}$ with respect to a not necessarily additive set function $c : \mathcal{F} \rightarrow \mathbb{R}$. Schmeidler (1986) extended Choquet’s definition by eliminating the non-negativity of $X$. We call (1.17) the Choquet integral, though the elements in $L^\infty$ are only $\mathbb{P}$-almost surely bounded, due to Carlier and Dana (2003). The function $\Psi \circ P$ appeared in (1.17) is called the concave distortion.

The robust representation of $\rho$ is given by Corollary 4.74 of Föllmer and Schied (2004), by using the uniform preference of two probability measures (also known as the second order stochastic dominance).

**Definition 1.8.** Let $\mu, \nu$ be two probability measures. $\mu$ is uniformly preferred over $\nu$,
written as $\mu \succeq_{\text{uni}} \nu$, if for all utility functions $u$,

$$\int ud\mu \geq \int ud\nu.$$  

Note that a utility function $u$ is a function $u : \mathbb{R} \to \mathbb{R}$ which is strictly concave and strictly increasing.

Föllmer and Schied (2004) showed that $\rho_{\mu}$ has the following robust representation:

$$\rho_{\mu}(X) = \sup_{Q \in Q_{\mu}} \mathbb{E}_{Q}[-X],$$  \hspace{1cm} (1.19)

where

$$Q_{\mu} := \left\{ Q \in Q : P \circ \left( \frac{dQ}{dP} \right)^{-1} \succeq_{\text{uni}} L \circ (\phi)^{-1} \right\},$$  \hspace{1cm} (1.20)

and $L$ denotes the Lebesgue measure. Note that the supremum in (1.19) can be attained if and only if $\mu(\{0\}) = 0$, and in this case, an “optimal” measure $Q_X$ has the density $\frac{dQ_X}{dP} =: f(X)$ given by

$$f(x) = \begin{cases} 
\Psi'(F_X(x)) & \text{if } x \text{ is a continuous point of } F_X, \\
\frac{1}{F_X(x)-F_X(x-)} \int_{F_X(x-)}^{F_X(x)} \Psi'(t) dt & \text{otherwise}.
\end{cases}$$
In Chapter 1, as examples, we looked at risk measures including the Value-at-Risk and the Conditional Value-at-Risk. Both risk measures depend on the quantiles of the probability distributions of the financial positions up to some predetermined level. This level, also called the significance level and denoted by $\lambda$, is some real number $\lambda$ between 0 and 1. When the value of $\lambda$ is fixed, the probability distributions of the financial positions beyond $\lambda$ are irrelevant to the value of $VaR_\lambda$ and $CVaR_\lambda$. We call these kind of risk measures the $\lambda$-quantile dependent risk measures. In this chapter, we give the mathematical definition of the $\lambda$-quantile dependent convex risk measure and propose its robust representation.

2.1 The $\lambda$-quantile dependent convex risk measure and the $\lambda$-quantile Fatou property

We define the $\lambda$-quantile dependent convex risk measure as the following:

**Definition 2.1. ($\lambda$-quantile dependent convex risk measure)** Fix $\lambda \in (0, 1)$. A convex measure of risk $\rho : L^p \to \mathbb{R} \cup \{\infty\}$, $1 \leq p \leq \infty$, is $\lambda$-quantile dependent if for any $X, Y \in \mathcal{X}$,

$$X1_{\{X \leq q_\lambda^+(\lambda)\}} = Y1_{\{Y \leq q_\lambda^+(\lambda)\}} \quad \mathbb{P} - \text{a.s. implies } \rho(X) = \rho(Y).$$

Namely, the value of the risk measure $\rho$ depends on the random variables only up to a given significance level $\lambda$.

As discussed in Chapter 1, for a convex measure of risk on $L^p$, the Fatou property is an essential condition to make it representable. This is also true for the $\lambda$-quantile dependent convex measures of risk. However, in this case, we use the $\lambda$-quantile Fatou property to substitute the Fatou property while maintaining the representability of the risk measure.
Definition 2.2. (λ-quantile Fatou property) Fix \( \lambda \in (0,1) \). A convex measure of risk \( \rho : L^p \rightarrow \mathbb{R} \cup \{\infty\} \) has the \( \lambda \)-quantile Fatou property if for any sequence \( (X_n) \subset L^p \) such that \( \bar{q}^X_{X_n}(\lambda) \leq c_\lambda \) for some \( c_\lambda \in \mathbb{R} \) and for all \( n \in \mathbb{N} \), \( X_n \rightarrow X \) \( \mathcal{P} \)-a.s. for some \( X \in L^p \) implies \( \rho(X) \leq \liminf n \rightarrow \infty \rho(X_n) \).

Remark. We have the following remarks on the evolution of the Fatou property developed over time for different spaces:

1. Let us recall the original Fatou property defined by Delbaen (2002) for a finite coherent measure of risk \( \rho \) on the space \( L^\infty \): for any sequence \( (X_n) \subset L^\infty \) with \( |X_n| \leq C \) for some constant \( C \), \( X_n \rightarrow X \) \( \mathcal{P} \)-a.s. for some \( X \in L^\infty \) implies \( \rho(X) \leq \liminf n \rightarrow \infty \rho(X_n) \). We also recall the Fatou property of a convex measure of risk defined on the space \( L^p \), \( 1 \leq p \leq \infty \), given by Biagini and Frittelli (2009): for any sequence \( (X_n) \subset L^p \) such that for some \( Y \in L^p \), \( |X_n| \leq Y \) \( \mathcal{P} \)-a.s., \( X_n \rightarrow X \) \( \mathcal{P} \)-a.s. for some \( X \in L^p \) implies \( \rho(X) \leq \liminf n \rightarrow \infty \rho(X_n) \). In Definition 2.2 where we introduce the \( \lambda \)-quantile Fatou property, the upper \( \lambda \)-quantiles of the sequence \( (X_n) \) is uniformly bounded above by some constant which depends on the level \( \lambda \). The boundedness in the \( \lambda \)-quantile Fatou property is the weakest in the sense that more sequences of random variables satisfy this condition, and therefore, the continuity condition turns out to be the strongest. In conclusion, we have the following implication: \( \rho \) has \( \lambda \)-quantile Fatou property \( \Rightarrow \rho \) has the Fatou property of Biagini and Frittelli \( \Rightarrow \rho \) has the Fatou property of Delbaen.

2. The uniform boundedness of the upper quantiles \( \bar{q}^X_{X_n} \) in Definition 2.2 is easier to handle compared with finding a dominant random variable \( Y \) for the whole sequence \( (X_n) \). As in practice we are mostly concerned about the losses of the financial positions, a natural choice of \( c_\lambda = 0 \) is already included.
2.2 The robust representation of the \( \lambda \)-quantile dependent convex risk measure

Similar to Theorem 1.3 and Theorem 1.4, we can give the robust representation for the \( \lambda \)-quantile dependent convex risk measure. For the preparation of the proof, we recall some theorems and Lemmas.

**Theorem 2.1.** (S.Mazur) The closure and weak closure of a convex subset of a normed space are the same. In particular, a convex subset of a normed space is closed if and only if it is weakly closed.

Besides, the following Lemma appeared as Exercise 2.84 of Megginson (1988). It states an analogues result between the norm and weak topologies to the Krein-Šmulian theorem on weakly* closed convex sets. For completeness, we give the proof here.

**Lemma 2.1.** Let \( C \) be a convex subset of a normed space \((X, \| \cdot \|)\).

1. \( C \) is closed if and only if \( C \cap \{ x \in X : \| x \| \leq t \} \) is closed for all \( t > 0 \).

2. \( C \) is weakly closed if and only if \( C \cap \{ x \in X : \| x \| \leq t \} \) is weakly closed for all \( t > 0 \).

**Proof.**

1. If \( C \) is closed, then it is obvious that \( C \cap \{ x \in X : \| x \| \leq t \} \) is closed. Suppose now for any \( t > 0 \), \( C \cap \{ x \in X : \| x \| \leq t \} \) is closed. Let \((c_n)\) be a sequence in \( C \) converging to some \( c \) in norm. Then for \( \epsilon > 0 \) there is some \( N \in \mathbb{N} \) such that for every \( n \geq N \), \( \|c_n\| \leq \|c\| + \epsilon \). Taking \( t = \|c\| + \epsilon \), then \((c_n)_{n> N} \subset C \cap \{ x \in X : \| x \| \leq t \} \). Since the set \( C \cap \{ x \in X : \| x \| \leq t \} \) is closed, \( c \in C \cap \{ x \in X : \| x \| \leq t \} \) and therefore \( c \in C \).

2. Since for any \( t > 0 \) the closed ball \( \{ x \in X : \| x \| \leq t \} \) is convex, it is weakly closed by Theorem 2.1. Therefore, if \( C \) is weakly closed, so is \( C \cap \{ x \in X : \| x \| \leq t \} \). Conversely, suppose for any \( t > 0 \), \( C \cap \{ x \in X : \| x \| \leq t \} \) is weakly closed, then since the intersection of two convex sets is still convex, again by Theorem 2.1, \( C \cap \{ x \in X : \| x \| \leq t \} \) is strongly (norm) closed. Thus \( C \) is strongly closed. Since \( C \) is convex, it is weakly closed. \( \diamond \)

The following two Lemmata, Lemma 2.2 and Lemma 2.3, are quoted from Fôlmer and Schied (2004), where a short proof was given to Lemma 2.2 and a more precise proof was proposed to Lemma 2.3.
Lemma 2.2. Suppose that $E$ is a locally convex space and that $C$ is a convex subset of $E$. Then $C$ is weakly closed if and only if $C$ is closed in the original topology of $E$.

Lemma 2.3. A convex subset $C$ of $L^\infty$ is weak* closed if for every $r > 0$, the set

$$C_r := C \cap \{X \in L^\infty : \|X\|_\infty \leq r\}$$

is closed in $L^1$.

For the $\lambda$-quantile dependent convex risk measure $\rho$ considered below, we make the following assumption:

**Assumption 2.1.** Let $\lambda \in (0, 1)$ be given. $\rho : L^p \to \mathbb{R} \cup \{\infty\}$, $1 \leq p \leq \infty$, is a proper $\lambda$-quantile dependent convex measure of risk.

The following theorem states the robust representation of the $\lambda$-quantile dependent convex risk measure as well as the equivalent conditions. This theorem is comparable to Theorem 1.3 and Theorem 1.4 for the convex measure of risk.

**Theorem 2.2.** Suppose Assumption 2.1 holds. The following statements are equivalent:

1. For $1 \leq p < \infty$, $\rho$ is $\sigma(L^p, L^q)$-lower semicontinuous, where $\sigma(L^p, L^q)$ indicates the weak topology on $L^p$; For $p = \infty$, $\rho$ is $\sigma(L^\infty, L^1)$-lower semicontinuous, where $\sigma(L^\infty, L^1)$ indicates the weak* topology on $L^\infty$.

2. For all $X \in L^p$, $\rho(X)$ has the following representation:

$$\rho(X) = \sup_{Q \in \mathcal{Q}_p} (\mathbb{E}_Q[-X] - \rho^*(Q)),$$

where $\rho^*$ is the Fenchel-Legendre transformation of $\rho$:

$$\rho^*(Q) = \sup_{X \in L^p} (\mathbb{E}_Q[-X] - \rho(X)),$$
and \( Q_p \) is defined by (1.7) in Chapter 1:

\[
Q_p := \left\{ \text{Q probability measure on } (\Omega, \mathcal{F}, P) : Q \ll P \text{ and } \frac{dQ}{dP} \in L^q \right\},
\]

3. For all \( X \in L^p \), \( \rho(X) \) has the following representation:

\[
\rho(X) = \sup_{Q \in \mathcal{Q}_p} \left( \mathbb{E}_Q[-X 1_{\{X \leq q_X^+(\lambda)\}}] - q_X^+(\lambda)Q(X > q_X^+(\lambda)) - \rho^*(Q) \right), \tag{2.3}
\]

with

\[
\rho^*(Q) = \sup_{X \in \mathcal{A}_\rho} \mathbb{E}_Q[-X] = \sup_{X \in \mathcal{A}_\rho} \left( \mathbb{E}_Q[-X 1_{\{X \leq q_X^+(\lambda)\}}] - q_X^+(\lambda)Q(X > q_X^+(\lambda)) \right), \tag{2.4}
\]

where the acceptance set is defined as

\[
\mathcal{A}_\rho := \{ X \in L^p \mid \rho(X) \leq 0 \}.
\]

4. \( \rho \) is continuous from above: For any sequence \( (X_n) \) in \( L^p \), \( X_n \searrow X \) \( P \)-a.s. implies

\[
\rho(X_n) \nearrow \rho(X).
\]

5. \( \rho \) has the \( \lambda \)-quantile Fatou property.

**Proof.** We adapt the proof of Theorem 4.31 of Föllmer and Schied (2004) and of Theorem 3.1 of Kaina and Rüschendorf (2009) for the proof of the theorem. First, we show that “1\( \Rightarrow \)2\( \Rightarrow \)4\( \Rightarrow \)1.”

“1\( \Rightarrow \)2” : This is true due Theorem 1.2. Note that for \( 1 \leq p < \infty \), the dual space of \((L^p, \| \cdot \|_p)\) is \( L^q \) with \( \frac{1}{p} + \frac{1}{q} = 1 \), and for \( p = \infty \), the dual space of \((L^\infty, \sigma(L^\infty, L^1))\) is \( L^1 \). Therefore, due to Theorem 1.2, we have \( \rho = \rho^{**} \), where \( \rho^{**} \) is the Fenchel-Legendre transform of \( \rho^* \), the Fenchel-Legendre transform of \( \rho \) defined by Definition 1.8. We need to verify \( \rho^* \) and \( \rho^{**} \) of the form (2.2) and (2.1). First, consider the case of \( 1 \leq p < \infty \). Let \( \ell \) be the linear functional from \( L^p \) to \( \mathbb{R} \). By Definition 1.8,

\[
\rho^*(\ell) = \sup_{X \in L^p} (\ell(X) - \rho(X)),
\]
and

\[ \rho^{**}(X) = \sup_{\ell \in L^q} (\ell(X) - \rho^*(\ell)). \]

The monotonicity and cash invariance of \( \rho \) (Definition 1.1) implies that \( \ell(X) \leq 0 \) for \( X \geq 0 \), and \( \ell(1) = -1 \) for all \( \ell \in L^q \) such that \( \rho^*(\ell) < \infty \). More precisely, for \( X \in L^p \) and \( X \geq 0 \), \( nX \geq X \). If \( \rho^*(\ell) < \infty \), then

\[ \ell(nX) - \rho(nX) \leq \rho^*(\ell) \Rightarrow n\ell(X) \leq \rho(nX) + \rho^*(\ell) \leq \rho(X) + \rho^*(\ell), \]

the last inequality is due to the monotonicity of \( \rho \). Therefore,

\[ \ell(X) \leq \frac{1}{n}(\rho(X) + \rho^*(\ell)) \to 0, \quad \text{as } n \to \infty, \]

which implies \( \ell(X) \leq 0 \) for all \( X \geq 0 \). In particular, due to the cash invariance of \( \rho \), for natural number \( n \),

\[ \ell(n) - \rho(n) \leq \rho^*(\ell) \Leftrightarrow n\ell(1) - \rho(0) + n \leq \rho^*(\ell) \Leftrightarrow \ell(1) \leq \frac{\rho(0) + \rho^*(\ell)}{n} - n \to -1, \text{as } n \to \infty, \]

and

\[ \ell(-n) - \rho(-n) \leq \rho^*(\ell) \Leftrightarrow -n\ell(1) - \rho(0) - n \leq \rho^*(\ell) \Leftrightarrow \ell(1) \geq -\frac{\rho(0) + \rho^*(\ell) + n}{n} \to -1, \text{as } n \to \infty. \]

These imply \( \ell(1) = -1 \). Thus, given \( \ell \in L^q \) with \( \rho^*(\ell) < \infty \), we can define a probability measure \( Q_{\ell} \) in the way that \( Q_{\ell}(A) := -\ell(1_A) = -\int_A \ell dP \), for \( A \in \mathcal{F} \). The Radon-Nikodým derivative of \( Q_{\ell} \) is given by \( \frac{dQ_{\ell}}{dP} = -\ell \). Therefore, for \( X \in L^p \), \( \ell(X) = E_{Q_{\ell}}[-X] \),

and \( \rho^*(\ell) = \rho^*(Q) = \sup_{X \in L^p} (E_{Q}[-X] - \rho(X)) \). If we define \( Q_p \) as of (1.7), then \( \rho^{**}(X) = \sup_{Q \in Q_p} (E_{Q}[-X] - \rho^*(Q)) \). Thus, we obtain statement 1 for \( 1 \leq p < \infty \). For the \( p = \infty \),

the argument is exactly same.

\[ 2 \Rightarrow 4 \]: Let \( (X_n) \subset L^p \) and \( X_n \searrow X \) \( \mathbb{P} \)-a.s. for \( X \in L^p \). We need to show \( \rho(X_n) \not\rightarrow \rho(X) \),
where $\rho(X_n)$ and $\rho(X)$ are given by statement 2. Due the Monotone Convergence Theorem,

$$
\rho(X) = \sup_{Q \in \mathcal{Q}_p} (\mathbb{E}_Q[-X] - \rho^*(Q))
$$

\leq \sup_{Q \in \mathcal{Q}_p} \left( \lim_{n \to \infty} \mathbb{E}_Q[-X_n] - \rho^*(Q) \right)

\leq \liminf_{n \to \infty} \sup_{Q \in \mathcal{Q}_p} (\mathbb{E}_Q[-X_n] - \rho^*(Q))

= \liminf_{n \to \infty} \rho(X_n).

On the other hand, by the monotonicity of $\rho$, $\rho(X_n) \leq \rho(X)$, for all $n$, implies that

$$
\limsup_{n \to \infty} \rho(X_n) \leq \rho(X).
$$

Thus, we obtain

$$
\limsup_{n \to \infty} \rho(X_n) \leq \rho(X) \leq \liminf_{n \to \infty} \rho(X_n),
$$

which implies $\rho(X_n) \downarrow \rho(X)$.

"4\Rightarrow1": Recall Definition 1.3, that $\rho$ is lower semicontinuous is equivalent to that the set $C := \{\rho \leq c\}$ is weakly closed for $1 \leq p < \infty$ or weak* closed for $p = \infty$, for all $c \in \mathbb{R}$.

We first look at the case of $1 \leq p < \infty$. Let $C_r := C \cap \{X \in L^p : \|X\|_p \leq r\}$ with $r > 0$.

From Lemma 2.1, we need to show that $C_r$ is weakly closed. Let $(X_n)$ be a sequence in $C_r$ such that $X_n \to X$ in $L^p$, then there is a subsequence $(X_{n_k})$ such that $X_{n_k} \to X$ $P$-a.s. Define $Y_n := \sup_{n_j \geq n} X_{n_j}$, then $Y_n \downarrow X$, and from 4, $\rho(Y_n) \not\nearrow \rho(X)$. Thus,

$$
\rho(X) = \lim_{n \to \infty} \rho(Y_n) \leq \liminf_{n \to \infty} \rho(X_n) \leq c,
$$

which implies that $X \in C$. Moreover, $X_n \to X$ in $L^p$ implies that $\|X\|_p \leq r$. Thus, we achieve $X \in C_r$, which means the set $C_r$ is norm (strongly) closed. Due to Lemma 2.2, $C_r$ is weakly closed.

For the case of $p = \infty$, the proof is very similar to the case of $1 \leq p < \infty$ except that in the last step, instead of using Lemma 2.2, we need the Lemma 2.3.

We now show the equivalence of 2, 3, and 5.
“2 ⇔ 3”: this is due to the $\lambda$-quantile dependence of $\rho$. More precisely, we have

$$\rho(X) = \sup_{Q \in \mathcal{Q}_p} (\mathbb{E}_Q[-X] - \rho^*(Q))$$

$$\leq \sup_{Q \in \mathcal{Q}_p} \left( \mathbb{E}_Q[-X1\{X \leq q^+_X(\lambda)\}] - q^+_X(\lambda)Q(X > q^+_X(\lambda)) - \rho^*(Q) \right)$$

$$= \rho \left( X1\{X \leq q^+_X(\lambda)\} + q^+_X(\lambda)1\{X > q^+_X(\lambda)\} \right)$$

$$= \rho(X).$$

Note that $\rho^*(Q)$ given by equation (2.2) in 2 is also known as the penalty function of the representation (2.1). Föllmer and Schied (2002) showed that

$$\rho^*(Q) = \sup_{X \in \mathcal{A}_\rho} \mathbb{E}_Q[-X],$$

where $\mathcal{A}_\rho := \{X \in L^p \mid \rho(X) \leq 0\}$ is the acceptance set of $\rho$. (2.4) follows from the fact that $X \in \mathcal{A}_\rho$ is equivalent to $X1\{X \leq q^+_X(\lambda)\} + q^+_X(\lambda)1\{X > q^+_X(\lambda)\} \in \mathcal{A}_\rho$.

We show the equivalence of statement 2 and statement 5.

“2 ⇒ 5”: Let $(X_n) \in L^p$ be a sequence satisfying $q^+_X(\lambda) \leq c_\lambda$ for some $c_\lambda \in \mathbb{R}$ and for all $n \in \mathbb{N}$ and $X_n \to X$ $\mathbb{P}$-a.s. for some $X \in L^p$. The goal is to show that $\rho(X) \leq \lim \inf(X_n)$. Define $Y_n := X_n1\{X_n \leq c_\lambda\} + c_\lambda1\{X_n > c_\lambda\}$ and $Y := X1\{X \leq c_\lambda\} + c_\lambda1\{X > c_\lambda\}$. Then $Y_n \to Y$ $\mathbb{P}$-a.s. Since $\rho$ is $\lambda$-quantile dependent, $\rho(Y_n) = \rho(X_n)$ and $\rho(Y) = \rho(X)$. Define $Z_n(\omega) := \sup_{k \geq n} Y_k(\omega)$ for all $\omega \in \Omega$, then $Z_n \searrow \lim \sup Y_n = Y$. Thus, by statement 3, $\rho(Y) = \lim_{n \to \infty} \rho(Z_n)$. Since $Z_n(\omega) \geq Y_n(\omega)$ for all $\omega \in \Omega$, the monotonicity of $\rho$ implies that $\rho(Z_n) \leq \rho(Y_n)$. Therefore, $\rho(Y) \leq \lim \inf \rho(Y_n)$. By the $\lambda$-quantile dependence of $\rho$, we obtain $\rho(X) \leq \lim \inf \rho(X_n)$.

“5 ⇒ 2”: Suppose $\rho$ has the $\lambda$-quantile Fatou property. We first show that $\rho$ is $\sigma(L^p, L^q)$-lower semicontinuous for $1 \leq p < \infty$. This is equivalent to show that the convex subset $\mathcal{C} := \{\rho \leq c\} \subset L^p$ is weakly closed for any fixed constant $c$. By Lemma 2.1 in the Appendix, an analogous result to the Krein-Šmulian Lemma, this is true if and only if $\mathcal{C}_r := \mathcal{C} \cap \{X \in L^p : \|X\|_p \leq r\}$ is weakly closed for all $r > 0$. Since the space $(L^p, \|\cdot\|_p)$, $1 \leq p < \infty$, is locally convex, that $\mathcal{C}_r$ is weakly closed is equivalent to that $\mathcal{C}_r$ is strongly.
closed. In the following, we will show that $C_r$ is strongly closed in $L^p$ with respect to the norm topology. Let $(X_n)$ be a sequence in $C_r$ converging to $X$ in $L^p$-norm. Then there is a subsequence $(X_{n_k})$ converging to $X$ $P$-a.s. If we can show that $(q_{X_{n_k}}^+(\lambda))$ is uniformly bounded above, then statement 4 implies $\rho(X) \leq \liminf \rho(X_{n_k}) \leq c$. Therefore, $X \in C_r$, i.e., $C_r$ is strongly closed.

To complete the proof, it remains to show that $(q_{X_{n_k}}^+(\lambda))$ is uniformly bounded from above. If this is not true, then for any $m \in \mathbb{N}$, there exists a $Y_m \in (X_{n_k})$ such that $q_{Y_m}^+(\lambda) > m$.

Thus

$$
\|Y_m\|_p^p = \int_{\{Y_m < q_{Y_m}^+(\lambda)\}} |Y_m|^p dP + \int_{\{Y_m \geq q_{Y_m}^+(\lambda)\}} |Y_m|^p dP \\
\geq m^p P(Y_m \geq q_{Y_m}^+(\lambda)) \geq m^p (1 - \lambda) \to \infty, \quad \text{as } m \to \infty.
$$

This is a contradiction to the fact that $Y_m \in C_r$. For the case $p = \infty$, apply Lemma 2.3 instead of Lemma 2.1, the remaining part of the proof is similar to the case $1 \leq p < \infty$. 

Under certain continuity conditions or when the convex risk measure is finitely valued, the supremum in representation (2.1) can be attained, see Biagini and Frettelli (2009) and Kaina and Rüschendorf (2009). In this case, we can further narrow the representation set in (2.3) so that the probability measures concentrate on relevant sets.

**Corollary 2.3.** Suppose $\rho : L^p \to \mathbb{R} \cup \{\infty\}$, $1 \leq p \leq \infty$, satisfies Assumption 2.1 and can be represented by

$$
\rho(X) = \max_{Q \in \mathcal{Q}} (\mathbb{E}_Q[-X] - \rho^*(Q)), \quad (2.5)
$$

where $\rho^*$ is defined in equation (2.2) and $\mathcal{Q} \subset \mathcal{Q}_p$. Then for each $X \in L^p$, there is a corresponding set $\mathcal{Q}_{\lambda,X}^p := \{Q \in \mathcal{Q}_p : Q(X > q_X^+(\lambda)) = 0\}$ such that

$$
\rho(X) = \max_{Q \in \mathcal{Q}_{\lambda,X}^p \cap \mathcal{Q}} (\mathbb{E}_Q[-X] - \rho^*(Q)) = \max_{Q \in \mathcal{Q}_{\lambda,X}^p \cap \mathcal{Q}} (\mathbb{E}_Q[-X 1_{\{X \leq q_X^+(\lambda)\}}] - \rho^*(Q)). \quad (2.6)
$$

**Proof.** For each $X \in L^p$, there exists a $Q_X \in \mathcal{Q}$ such that

$$
\rho(X) = \mathbb{E}_{Q_X}[-X] - \rho^*(Q_X).
$$
Define

\[ X_q := X1_{\{X \leq q^+X(\lambda)\}} + q^+X(\lambda)1_{\{X > q^+X(\lambda)\}}, \]  \hspace{1cm} (2.7) \]

then \( X_q1_{\{X \leq q^+X(\lambda)\}} = X1_{\{X \leq q^+X(\lambda)\}} P\)-a.s. and \( X_q \leq X P\)-a.s. By the \( \lambda \)-quantile dependence of \( \rho \),

\[ \rho(X_q) = \rho(X) = \mathbb{E}_{Q_X}[-X] - \rho^*(Q_X) \leq \mathbb{E}_{Q_X}[-X_q] - \rho^*(Q_X) \leq \rho(X_q). \]

This implies

\[ \rho(X_q) = \mathbb{E}_{Q_X}[-X] - \rho^*(Q_X) = \mathbb{E}_{Q_X}[-X_q] - \rho^*(Q_X). \]

Thus, \( \mathbb{E}_{Q_X}[(X - q^+X(\lambda))1_{\{X > q^+X(\lambda)\}}] = 0 \), which implies \( Q_X(X > q^+X(\lambda)) = 0 \). Since \( Q_X \in Q_{p}^{\lambda,X} \cap \mathcal{Q} \),

\[ \rho(X) = \mathbb{E}_{Q_X}[-X] - \rho^*(Q_X) \leq \max_{Q \in Q_{p}^{\lambda,X} \cap \mathcal{Q}} (\mathbb{E}_{Q}[-X] - \rho^*(Q)) = \max_{Q \in Q_{p}^{\lambda,X} \cap \mathcal{Q}} (\mathbb{E}_{Q}[-X1_{\{X \leq q^+X(\lambda)\}}] - \rho^*(Q)). \]

On the other hand, \( Q_{p}^{\lambda,X} \cap \mathcal{Q} \subset \mathcal{Q} \), representation (2.5) implies

\[ \rho(X) \geq \max_{Q \in Q_{p}^{\lambda,X} \cap \mathcal{Q}} (\mathbb{E}_{Q}[-X] - \rho^*(Q)) = \max_{Q \in Q_{p}^{\lambda,X} \cap \mathcal{Q}} (\mathbb{E}_{Q}[-X1_{\{X \leq q^+X(\lambda)\}}] - \rho^*(Q)). \]

\( \diamond \)
CHAPTER 3: \(\lambda\)-QUANTILE LAW INVARIANT CONVEX RISK MEASURE

As mentioned in Chapter 2, the conditional value of risk \(CVaR_{\lambda}\) for a given significance level \(\lambda\) is a \(\lambda\)-quantile dependent convex risk measure. In fact, it is \(\lambda\)-quantile law invariant in the sense that if two financial positions \(X\) and \(Y\) have the same probability distributions up to the level \(\lambda\), then \(CVaR_{\lambda}(X) = CVaR_{\lambda}(Y)\). In this section, we give the formal definition of the \(\lambda\)-quantile law invariant convex risk measure and study the robust representation.

**Definition 3.1.** (\(\lambda\)-quantile law invariant convex risk measure) Fix \(\lambda \in (0,1)\). A convex measure of risk \(\rho : L^p \to \mathbb{R} \cup \{\infty\}, 1 \leq p \leq \infty\), is \(\lambda\)-quantile law invariant, if for any \(X,Y \in \mathcal{X}\),

\[
X 1_{\{X \leq q_X^\nu(\lambda)\}} \text{ and } Y 1_{\{Y \leq q_Y^\nu(\lambda)\}} \text{ have the same law implies } \rho(X) = \rho(Y).
\]

Namely, the value of the risk measure \(\rho\) depends on the probability distribution of the random variables only up to a given significance level \(\lambda\).

Throughout this section, we assume \(\rho : L^p \to \mathbb{R} \cup \{\infty\}\) satisfies Assumption 2.1, i.e., \(\rho\) is a proper convex measure of risk. In addition, we fix \(\lambda \in (0,1)\) and use the notation \(X \overset{\lambda}{\sim} Y\) to denote that the random variables \(X\) and \(Y\) have the same probability distribution up to their \(\lambda\)-quantiles. And also, we use \(X \sim Y\) to denote that \(X\) and \(Y\) have the same probability distribution.

**Lemma 3.1.** Suppose the probability space \((\Omega, \mathcal{F}, P)\) is atomless. Let \(Q\) be a probability measure that is absolutely continuous with respect to \(P\). Define \(\varphi := \frac{dQ}{dP}\). If \(X \in L^p\) and \(\varphi \in L^q\), then

\[
\sup_{\tilde{X} \overset{\lambda}{\sim} X} \mathbb{E}_Q[-\tilde{X}] = \int_0^\lambda q_X(t)q_{-\varphi}(t)dt + q_X^\lambda(\lambda) \int_\lambda^1 q_{-\varphi}(t)dt.
\] (3.1)
The proof of Lemma 3.1 involves various results related to the quantile function $q_X(t)$ of a random variable $X$. These results are summarized in Lemma 3.2 through Lemma 3.4.

**Lemma 3.2.** Let $X$ be a random variable with a continuous cumulative distribution function $F_X$ and quantile function $q_X$. Define $U := F_X(X)$. Then $U$ is uniformly distributed on $(0, 1)$, and $X = q_X(U)$ $\mathbb{P}$-almost surely.

Lemma 3.2 is quoted from Lemma A.21 of Föllmer and Schied. A proof the lemma is also provided there.

The next lemma and its proof can be found in Lemma A.24 of Föllmer and Schied (2004). This Lemma provides a version of the “Hardy-Littlewood inequalities”. The original version of the Hardy-Littlewood inequalities can be found in Hardy, Littlewood, and Pólya (1952).

**Lemma 3.3.** Let $X$ and $Y$ be two random variables on $(\Omega, \mathcal{F}, \mathbb{P})$ with quantile functions $q_X$ and $q_Y$. Then

\[
\int_0^1 q_X(1-s)q_Y(s)ds \leq \mathbb{E}[XY] \leq \int_0^1 q_X(s)q_Y(s)ds,
\]

provided that all integrals are well defined. If $X = f(Y)$ and the lower (upper) bound is finite, then the lower (upper) bound is attained if and only if $f$ can be chosen as a decreasing (increasing) function.

The following lemma generalizes Lemma 4.55 of Föllmer and Schied (2004) from $L^\infty$ space to $L^p$ space.

**Lemma 3.4.** Suppose the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ is atomless. For random variables $X \in L^p$ and $Y \in L^q$, where $p, q \in [1, \infty]$ satisfying $\frac{1}{p} + \frac{1}{q} = 1$,

\[
\sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y] = \int_0^1 q_X(t)q_Y(t)dt.
\]

**Proof.** The idea of the proof is very similar to that of Lemma 4.55 of Föllmer and Schied (2004). First, the Hardy-Littlewood inequalities (3.2) ensures that $\mathbb{E}[\tilde{X}Y] \leq$
\[ \int_0^1 q_X(t)q_Y(t)dt = \int_0^1 q_X(t)q_Y(t)dt \text{ for all } \tilde{X} \sim X. \] Thus, \( \sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y] \leq \int_0^1 q_X(t)q_Y(t)dt. \)

In general, to show \( \sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y] \geq \int_0^1 q_X(t)q_Y(t)dt \), we first assume \( Y \) has continuous distribution. Define \( U := F_Y(Y) \), where \( F_Y(\cdot) \) is the cumulative distribution function of random variable \( Y \), then by Lemma 3.2, \( Y = q_Y(U) \) \( \mathbb{P} \)-a.s. Define \( \tilde{X} := q_X(U) \), then \( \tilde{X} \sim X \). Therefore, for such defined \( \tilde{X} \),

\[ \mathbb{E}[\tilde{X}Y] = \mathbb{E}[q_X(U)q_Y(U)] = \int_0^1 q_X(t)q_Y(t)dt. \]

So indeed we find some \( \tilde{X} \) that has the same law as \( X \) and attains \( \int_0^1 q_X(t)q_Y(t)dt \).

In the case that \( Y \) does not have continuous probability distribution, we define for \( n \geq 1 \)

\[ Y_n := Y + \frac{1}{n}Z1_{\{Y \geq q_Y(a)\}} - \frac{1}{n}Z1_{\{Y < q_Y(a)\}}, \]

where \( Z \in L^q \) is a nonnegative random variable having continuous probability distribution (such \( Z \) exists due to the atomlessness of the probability space), and the real number \( a \in [0, 1] \) is chosen such that \( q_X(t) \leq 0 \) for all \( t < a \) and \( q_X(t) \geq 0 \) for \( t > a \). Then \( Y_n \) has continuous probability distribution. For the quantile function \( q_{Y_n}(t) \), we have \( q_{Y_n}(t) \leq q_Y(t) \), for \( t < a \), and \( q_{Y_n}(t) \geq q_Y(t) \), for \( t > a \). We have

\[
\int_0^1 q_X(t)q_{Y_n}(t)dt = \int_0^a q_X(t)q_{Y_n}(t)dt + \int_a^1 q_X(t)q_{Y_n}(t)dt \\
\geq \int_0^a q_X(t)q_Y(t)dt + \int_a^1 q_X(t)q_Y(t)dt \\
= \int_0^1 q_X(t)q_Y(t)dt.
\]

Thus, by applying the Lemma for a continuously distributed random variable,

\[
\int_0^1 q_X(t)q_Y(t)dt \leq \int_0^1 q_X(t)dtq_{Y_n}(t)dt = \sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y_n].
\]

If we can show that

\[
\sup_{\tilde{X} \sim X} \mathbb{E}[XY_n] \to \sup_{\tilde{X} \sim X} \mathbb{E}[XY] \quad \text{as } n \to \infty,
\]
then we can conclude
\[
\int_0^1 q_X(t)q_Y(t)dt \leq \sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y]
\]
and finish the proof. For any \( \varepsilon > 0 \), there exist \( \tilde{X}_\varepsilon \sim X \) such that \( \mathbb{E}[\tilde{X}_\varepsilon Y_n] \geq \sup_{\tilde{X} \sim X} [\tilde{X}Y_n] - \varepsilon \). Then for arbitrary \( \varepsilon \),

\[
\sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y_n] - \sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y] \leq \mathbb{E}[\tilde{X}_\varepsilon Y_n] + \varepsilon - \mathbb{E}[\tilde{X}_\varepsilon Y] = \mathbb{E}[\tilde{X}_\varepsilon(Y_n - Y)] + \varepsilon
\]

\[
\leq \|\tilde{X}\|_p\|Y_n - Y\|_q + \varepsilon \leq \frac{2}{n}\|\tilde{X}\|_p\|Z\|_q + \varepsilon \rightarrow \varepsilon, \quad \text{as } n \rightarrow \infty.
\]

Thus, we get \( \limsup_{n \rightarrow \infty} \sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y_n] \leq \sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y] \). Similar argument leads to the opposite inequality \( \liminf_{n \rightarrow \infty} \sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y_n] \geq \sup_{\tilde{X} \sim X} \mathbb{E}[\tilde{X}Y], \) hence, the equality holds.

Based on Lemma 3.2 through Lemma 3.4, we are ready to show Lemma 3.1:

**Proof of Lemma 3.1.** By Lemma 3.4,

\[
\sup_{\tilde{X} \sim X} \mathbb{E}_Q[-\tilde{X}] = \sup_{\tilde{X} \sim X} (\sup_{\tilde{X} \sim X} \mathbb{E}_Q[-\tilde{X}])
\]

\[
= \sup_{\tilde{X} \sim X} (\sup_{\tilde{X} \sim X} \mathbb{E}[-\tilde{X}\varphi])
\]

\[
= \sup_{\tilde{X} \sim X} \left( \int_0^1 q_{\tilde{X}}(t)q_{-\varphi}(t)dt \right)
\]

\[
= \sup_{\tilde{X} \sim X} \left( \int_0^\lambda q_{\tilde{X}}(t)q_{-\varphi}(t)dt + \int_\lambda^1 q_{\tilde{X}}(t)q_{-\varphi}(t)dt \right)
\]

\[
\leq \int_0^\lambda q_X(t)q_{-\varphi}(t)dt + q_X^+(\lambda) \int_\lambda^1 q_{-\varphi}(t)dt.
\]

The last inequality is true since \( q_{-\varphi}(t) \leq 0 \) for \( t \in [0, 1] \) and \( \tilde{X} \overset{\lambda}{\sim} X \) implies \( q_{\tilde{X}}(t) \geq q_X^+(\lambda) \) for all \( t \in (\lambda, 1] \). The reverse inequality is true since

\[
X_q := X1_{\{X \leq q_X^+(\lambda)\}} + q_X^+(\lambda)1_{\{X > q_X^+(\lambda)\}} \overset{\lambda}{\sim} X,
\]
and therefore,

$$\int_0^\lambda q_X(t)q_{-\varphi}(t)dt + q_X^+(\lambda) \int_\lambda^1 q_{-\varphi}(t)dt \leq \sup_{\tilde{X} \sim X} \left( \int_0^\lambda q_{\tilde{X}}(t)q_{-\varphi}(t)dt + \int_\lambda^1 q_{\tilde{X}}(t)q_{-\varphi}(t)dt \right).$$

Hence, equation (3.1) is obtained. □

In the following theorem we state a representation of a $\lambda$-quantile law invariant convex risk measure. It is a $\lambda$-quantile version of Theorem 1.5 for the law invariant convex risk measure.

**Theorem 3.1.** Suppose the probability space $(\Omega, \mathcal{F}, P)$ is atomless. Let $\rho : L^p \rightarrow \mathbb{R} \cup \{\infty\}$ be a proper convex measure of risk (i.e., satisfy Assumption 2.1) that is $\lambda$-quantile law invariant. $\rho$ has the $\lambda$-quantile Fatou property if and only if $\rho$ has the following representation:

$$\rho(X) = \sup_{Q \in \mathcal{Q}} \left( \int_0^\lambda q_X(t)q_{-\varphi}(t)dt + q_X^+(\lambda) \int_\lambda^1 q_{-\varphi}(t)dt - \rho^*(Q) \right),$$

where $\varphi := \frac{dQ}{dP}$ for $Q \in \mathcal{Q}_p$ and

$$\rho^*(Q) = \sup_{X \in L^p} \left( \int_0^\lambda q_X(t)q_{-\varphi}(t)dt + q_X^+(\lambda) \int_\lambda^1 q_{-\varphi}(t)dt - \rho(X) \right)$$

**Proof.** By Theorem 2.2 and Lemma 3.1,

$$\rho^*(Q) = \sup_{X \in L^p} (\mathbb{E}_Q[-X] - \rho(X))$$

$$= \sup_{X \in L^p} \left( \sup_{\tilde{X} \sim X} (\mathbb{E}_Q[-\tilde{X}] - \rho(\tilde{X})) \right)$$

$$= \sup_{X \in L^p} \left( \sup_{\tilde{X} \sim X} (\mathbb{E}_Q[-\tilde{X}] - \rho(X)) \right)$$

$$= \sup_{X \in L^p} \left( \int_0^\lambda q_X(t)q_{-\varphi}(t)dt + q_X^+(\lambda) \int_\lambda^1 q_{-\varphi}(t)dt - \rho(X) \right).$$

For $X \in L^p$, let $X_q$ be defined as $X_q := X 1_{\{X \leq q_X^+\lambda(\lambda)\}} + q_X^+(\lambda)1_{\{X > q_X^+\lambda(\lambda)\}}$. Obviously, $X_q \sim X$. Since $\rho$ is $\lambda$-quantile law invariant, $\rho(X) = \rho(X_q)$. For $\tilde{Q}, Q \in \mathcal{Q}_p$, we use the notation $\tilde{Q} \sim Q$ to denote that the the Radon-Nikodým derivatives $\varphi_{\tilde{Q}}$ and $\varphi_Q$ have
same probability distribution. Notice that \( \rho^\ast \) depends on \( Q \) only through the probability distribution of its Radon-Nikodým derivative \( \varphi_Q \), so \( \rho^\ast(\tilde{Q}) = \rho^\ast(Q) \) if \( \varphi_{\tilde{Q}} \sim \varphi_Q \). Again, by Theorem 2.2 and Lemma 3.4,

\[
\rho(X) = \rho(X_q) = \sup_{Q \in Q_p} \left( \mathbb{E}_Q[-X_q] - \rho^\ast(Q) \right) \\
= \sup_{Q \in Q_p} \left( \sup_{\tilde{Q} \sim \varphi_Q} \left( \mathbb{E}_Q[-\varphi_{\tilde{Q}}] - \rho^\ast(\tilde{Q}) \right) \right) \\
= \sup_{Q \in Q_p} \left( \sup_{\tilde{Q} \sim \varphi_Q} \mathbb{E}_Q[-\varphi_{\tilde{Q}}] - \rho^\ast(\tilde{Q}) \right) \\
= \sup_{Q \in Q_p} \left( \int_0^\Lambda q_X(t)q_{-\varphi_Q}(t)dt + \lambda q_X^+(\lambda) \int_0^1 q_{-\varphi_Q}(t)dt - \rho^\ast(Q) \right).
\]

Hence, if we denote \( \varphi_Q \) by \( \varphi \) for simplicity, then

\[
\rho(X) = \sup_{Q \in Q_p} \left( \int_0^\Lambda q_X(t)q_{-\varphi}(t)dt + \lambda q_X^+(\lambda) \int_0^1 q_{-\varphi}(t)dt - \rho^\ast(Q) \right).
\]

\[\square\]

**Remark.** Theorem 1.5 proposes a representation of the law invariant convex risk measure \( \rho : L^\infty \to \mathbb{R} \). Due to Lemma 3.4, theorem 1.5 can be extended to the law invariant convex risk measure \( \rho : L^p \to \mathbb{R} \cup \{\infty\} \) with \( 1 \leq p \leq \infty \), provided that \( \rho \) is proper. More precisely, we have the following proposition:

**Proposition 3.2.** Let \( \rho : L^p \to \mathbb{R} \cup \{\infty\} \), \( 1 \leq p \leq \infty \), satisfy Assumption 2.1 and have the Fatou property formulated in Theorem 1.4. Then \( \rho \) is law invariant if and only if it can be represented as

\[
\rho(X) = \sup_{Q \in Q_p^1} \left( \int_0^1 q_X(t)q_{-\varphi_Q}(t)dt - \rho^\ast(Q) \right),
\]

where \( \varphi_Q := \frac{\partial \rho}{\partial P} \), and

\[
\rho^\ast(Q) = \sup_{X \in L^p} \left( \int_0^1 q_X(t)q_{-\varphi_Q}(t)dt - \rho(X) \right) = \sup_{X \in A_p} \int_0^1 q_X(t)q_{-\varphi_Q}(t)dt,
\]
where $Q_p = \{ Q \text{ probability measure on } (\Omega, \mathcal{F}, P) : Q \ll P, \frac{dQ}{dP} \in L^q \text{ with } \frac{1}{p} + \frac{1}{q} = 1 \}$, and $A_\rho$ is the acceptance set of $\rho$. 
In Chapter 1, we introduced the Weighted Value-at-Risk \( \rho_\mu(X) := \int_{[0,1]} CVaR_\gamma(X) \mu(d\gamma) \) with \( \mu \) a probability measure on \((0,1]\). In this chapter, we study the \( \lambda \)-quantile dependent Weighted Value-at-Risk defined on \( L^p \) space, \( 1 \leq p \leq \infty \). Throughout this chapter, the probability space \((\Omega, \mathcal{F}, P)\) is assumed to be atomless.

**Definition 4.1.** The \( \lambda \)-quantile dependent Weighted Value-at-Risk is a mapping \( \rho_{\mu,\lambda} : L^p \rightarrow \mathbb{R} \cup \{\infty\}, \ 1 \leq p \leq \infty \), defined as

\[
\rho_{\mu,\lambda}(X) = \int_{[0,\lambda]} CVaR_\gamma(X) \mu(d\gamma),
\]

where \( \lambda \in (0,1) \) is fixed, \( \mu \) is a probability measure on \([0,\lambda]\) satisfying \( \mu(\{0\}) = 0 \), and \( CVaR_\gamma(X) = -\frac{1}{\gamma} \int_0^\gamma q_X^+(t) dt \) is the Conditional Value-at-Risk at level \( \gamma \).

Under the assumption of \( \mu(\{0\}) = 0 \) in Definition 4.1, we can alternatively define \( \rho_{\mu,\lambda}(X) := \int_{(0,\lambda]} CVaR_\gamma(X) \mu(d\gamma) \). Note that \( \rho_{\mu,\lambda} \) is a coherent measure of risk. Applying the Fubini’s theorem, we easily obtain an equivalent form of \( \rho_{\mu,\lambda} \):

\[
\rho_{\mu,\lambda}(X) = -\int_0^\lambda q_X(t) \phi(t) dt,
\]

where \( \phi(t) = \int_{[t,\lambda]} \frac{1}{s} \mu(ds) \) for \( t \in (0,\lambda] \). Hence, the measure of risk \( \rho_{\mu,\lambda} \) is \( \lambda \)-quantile law invariant.

**Remark.**

- Take \( \lambda \) as 1 and \( \mu \) as a probability measure on \([0,1]\), then (4.1) defines the Weighted Value-at-Risk \( \rho_\mu = \int_{[0,1]} CVaR_\gamma(X) \mu(d\gamma) \). For a given \( \lambda \in (0,1) \), the Weighted Value-at-Risk \( \rho_\mu \) is \( \lambda \)-quantile dependent if and only if \( \mu([0,\lambda]) = 1 \).
Acerbi (2002) defined the Spectral Measure of Risk \( M_\tilde{\phi}(X) = -\int_0^1 q_X(t)\tilde{\phi}(t)dt \), where \( \tilde{\phi}(t) := \int_t^1 \mu(d\gamma) \) and \( \mu \) is some measure on \([0, 1]\) (not necessarily a probability measure). He showed that \( M_\tilde{\phi} \) is a coherent measure of risk, if \( \tilde{\phi} \) satisfies the admissibility conditions: \( \tilde{\phi} \) is positive, decreasing and \( \|\tilde{\phi}\| = \int_0^1 |\tilde{\phi}(p)|dp = 1 \). Acerbi interpreted the function \( \tilde{\phi} \) as the “risk spectrum”. For given \( \lambda \in (0, 1) \), take \( \tilde{\phi}(t) = \frac{1}{\lambda}1_{\{0 \leq t \leq \lambda\}} \), then \( CVaR_\lambda(X) = M_\tilde{\phi}(X) \). In this case, the function \( \tilde{\phi}(t) \) is the density of a uniform distribution on \([0, \lambda]\), \( \tilde{\phi} \) assigns equal weights to every possible outcome under the threshold \( \lambda \), so \( CVaR \) represents the average of \( \lambda \)100% worst losses of a financial position.

The \( \lambda \)-quantile dependent coherent risk measure \( \rho_{\mu,\lambda} \) defined by either (4.1) or (4.2) can be interpreted in a similar way. In (4.2), the function \( \phi(t) \) assigns weights to the Value-at-Risk \(-q_X(t)\) for \( 0 \leq t \leq \lambda \), a reason associated to the name of \( \rho_{\mu,\lambda} \): the \( \lambda \)-quantile dependent Weighted Value-at-Risk. In Subsection 4.3.2, we will see a new example when the probability measure \( \mu \) in (4.1) is uniformly distributed on \([0, \lambda]\). \( \rho_{\mu,\lambda} \) averages the Conditional Value-at-Risk with equal weights up to the level \( \lambda \) and the “risk spectrum” in (4.2) turns out to be a natural logarithmic function.

4.1 The relationship between the \( \lambda \)-quantile uniform preference and the core of \( \lambda \)-quantile dependent concave distortion

In this section, we extend the definitions of uniform preference and core of a concave distortion to the \( \lambda \)-quantile case. We confirm the relationship between the two discovered by Carlier and Dana (2003) holds in the \( \lambda \)-quantile case. This prepares for the robust representation of the \( \lambda \)-quantile dependent Weighted Value-at-Risk \( \rho_{\mu,\lambda} \) in the next section.

4.1.1 \( \lambda \)-quantile uniform preference of two probability distribution measures

In this subsection, \( \mu \) denotes a probability distribution measure on \((\Omega_1, F_1)\) and \( \nu \) denotes a probability distribution measure on \((\Omega_2, F_2)\). We first define the “\( \lambda \)-quantile uniform preference” of two probability distribution measures. Recall that a quantile func-
tion of distribution measure \( \nu \) is denoted by \( q_\nu(\cdot) \) and satisfies
\[
\nu((\infty, q_\nu(t)] \geq t \quad \text{and} \quad \nu((\infty, q_\nu(t))] \leq t.
\] (4.3)

Similarly, \( q_\mu(\cdot) \) is a quantile function of distribution measure \( \mu \). We do not restrict the definition to be on the upper quantile function.

**Definition 4.2.** (\( \lambda \)-quantile uniform preference) Fix \( \lambda \in (0, 1) \). The probability distribution measure \( \mu \) is \( \lambda \)-quantile uniformly preferred over \( \nu \), denoted by \( \mu \succeq_{\text{uni}(\lambda)} \nu \), if
\[
\int_0^t q_\mu(s)ds \geq \int_0^t q_\nu(s)ds, \quad \text{for all } 0 < t \leq \lambda.
\]

**Remark.** For two random variables \( X \) and \( Y \) defined on two probability spaces \((\Omega_1, \mathcal{F}_1, \mathbb{P}_1)\) and \((\Omega_2, \mathcal{F}_2, \mathbb{P}_2)\), we can similarly define the \( \lambda \)-quantile uniform preference of the random variables \( X \) and \( Y \) in the sense of the \( \lambda \)-quantile uniform preference of their respective probability distribution measures \( \nu_X \) and \( \nu_Y \):
\[
X \succeq_{\text{uni}(\lambda)} Y \iff \nu_X \succeq_{\text{uni}(\lambda)} \nu_Y \iff \int_0^t q_{\nu_X}(s)ds \geq \int_0^t q_{\nu_Y}(s)ds, \quad \text{for all } 0 < t \leq \lambda.
\]

The uniform preference of two probability distribution measures (Definition 1.8) is also known as the second order stochastic dominance. Definition 4.2 can be viewed as the \( \lambda \)-quantile dependent version of the second order stochastic dominance. The following theorem gives the equivalent conditions of the \( \lambda \)-quantile uniform preference of two probability distribution measures \( \mu \) and \( \nu \).

Let us recall that a utility function \( u : \mathbb{R} \to \mathbb{R} \) is a strictly concave, strictly increasing and continuous function. We define a \( \nu \)-\( \lambda \)-quantile utility function \( u_{\nu,\lambda} : \mathbb{R} \to \mathbb{R} \) as
\[
u_{\nu,\lambda}(x) = u(x)1_{\{x \leq q_\nu(\lambda)\}} + u(q_\nu(\lambda))1_{\{x > q_\nu(\lambda)\}},
\] (4.4)
with $u$ a real-valued utility function on $\mathbb{R}$.

**Theorem 4.1.**

**a.** $\mu \succsim_{\text{uni}(\lambda)} \nu$ if and only if for all decreasing functions $h : (0, \lambda] \to \mathbb{R}^+$, the following is true:

$$\int_0^\lambda h(t)q_\mu(t)dt \geq \int_0^\lambda h(t)q_\nu(t)dt,$$

where $q_\mu$ and $q_\nu$ are quantile functions of $\mu$ and $\nu$.

**b.** The following equivalent conditions implies $\mu \succsim_{\text{uni}(\lambda)} \nu$:

1. For all $\nu$-$\lambda$-quantile utility function $u_{\nu,\lambda} : \mathbb{R} \to \mathbb{R}$, the following is true:

$$\int_{\mathbb{R}} u_{\nu,\lambda}(x)\mu(dx) \geq \int_{\mathbb{R}} u_{\nu,\lambda}(x)\nu(dx).$$

2. For all increasing, concave and continuous functions $f$ on $\mathbb{R}$ such that $f(x) = f(q_\nu(\lambda))$ for all $x \geq q_\nu(\lambda)$,

$$\int_{\mathbb{R}} f(x)\mu(dx) \geq \int_{\mathbb{R}} f(x)\nu(dx).$$

3. $\int_{\mathbb{R}} (c - x)^+\mu(dx) \leq \int_{\mathbb{R}} (c - x)^+\nu(dx)$, for all $c \leq q_\nu(\lambda)$.

4. Let $F_\mu$ and $F_\nu$ denote the distribution functions of $\mu$ and $\nu$, then

$$\int_{-\infty}^c F_\mu(x)dx \leq \int_{-\infty}^c F_\nu(x)dx,$$

for all $c \leq q_\nu(\lambda)$.

**c.** $\mu \succsim_{\text{uni}(\lambda)} \nu$ implies the following equivalent conditions:

1. For all $\mu$-$\lambda$-quantile utility function $u_{\mu,\lambda} : \mathbb{R} \to \mathbb{R}$, the following is true:

$$\int_{\mathbb{R}} u_{\mu,\lambda}(x)\mu(dx) \geq \int_{\mathbb{R}} u_{\mu,\lambda}(x)\nu(dx).$$
2. For all increasing, concave and continuous functions $f$ on $\mathbb{R}$ such that $f(x) = f(q_{\mu}(\lambda))$ for all $x \geq q_{\mu}(\lambda)$,

$$\int_{\mathbb{R}} f(x) \mu(dx) \geq \int_{\mathbb{R}} f(x) \nu(dx).$$

3. 

$$\int_{\mathbb{R}} (c-x)^+ \mu(dx) \leq \int_{\mathbb{R}} (c-x)^+ \nu(dx), \quad \text{for all } c \leq q_{\mu}(\lambda).$$

4. Let $F_{\mu}$ and $F_{\nu}$ denote the distribution functions of $\mu$ and $\nu$, then

$$\int_{-\infty}^{c} F_{\mu}(x) dx \leq \int_{-\infty}^{c} F_{\nu}(x) dx, \quad \text{for all } c \leq q_{\mu}(\lambda).$$

**Proof.**

"a": Take $h = 1_{(0,t)}$, $0 < t \leq \lambda$, then the “if” part is obviously true. For the proof of the “only if” part, since $h$ is decreasing, without loss of generality, we may assume that $h$ is left-continuous. Then a Radon measure $\eta$ on $[0, \lambda]$ can be defined by $h(t) - h(\lambda) = \eta([t, \lambda])$.

By Fubini’s theorem,

$$\int_{0}^{\lambda} h(t) q_{\mu}(t) dt = \int_{0}^{\lambda} h(\lambda) q_{\mu}(t) dt + \int_{0}^{\lambda} \int_{[t, \lambda]} \eta(ds) q_{\mu}(t) dt$$

$$= \int_{0}^{\lambda} h(\lambda) q_{\mu}(t) dt + \int_{[0, \lambda]} \int_{0}^{s} q_{\mu}(t) dt \eta(ds)$$

$$\geq \int_{0}^{\lambda} h(\lambda) q_{\nu}(t) dt + \int_{[0, \lambda]} \int_{0}^{s} q_{\nu}(t) dt \eta(ds)$$

$$= \int_{0}^{\lambda} h(t) q_{\nu}(t) dt.$$

"b": “1$\Rightarrow$2”: That the statement 2 implies the statement 1 is obvious. To show “ 1$\Rightarrow$2”, let $u_0$ be a utility function such that $\int_{\mathbb{R}} u_0 d\mu$ and $\int_{\mathbb{R}} u_0 d\nu$ are finite. Define $u(x) := u_0(x)1_{\{x \leq q_{\nu}(\lambda)\}} + u_0(q_{\nu}(\lambda)) 1_{\{x > q_{\nu}(\lambda)\}}$. Then $u$ is a $\nu$-$\lambda$-quantile utility function. For $\alpha \in (0, 1)$ define

$$u_{\alpha}(x) = \alpha f(x) + (1 - \alpha) u(x),$$
where \( f \) is an increasing concave and continuous function with \( f(x) = u_0(q_\nu(\lambda)) \) for \( x \geq q_\nu(\lambda) \). Then, we have

\[
u_\alpha(x) = \begin{cases} \alpha f(x) + u_0(x) & \text{for } x \leq q_\nu(\lambda), \\ u_0(q_\nu(\lambda)) & \text{for } x > q_\nu(\lambda). \end{cases}
\]

For \( x \leq q_\nu(\lambda) \), \( \nu_\alpha(x) \) is strictly increase, strictly concave and continuous. Thus, \( \nu_\alpha \) is a \( \nu_\lambda \)-quantile utility function. Statement 1 implies

\[
\int_{\mathbb{R}} \nu_\alpha(x)\mu(dx) \geq \int_{\mathbb{R}} \nu_\alpha(x)\nu(dx).
\]

Substituting \( \nu_\alpha \) into this inequality and letting \( \alpha \) goes to 1, yields

\[
\int_{\mathbb{R}} f(x)\mu(dx) = \lim_{\alpha \to 1} \int_{\mathbb{R}} \nu_\alpha(x)\mu(dx) \geq \lim_{\alpha \to 1} \int_{\mathbb{R}} \nu_\alpha(x)\nu(dx) = \int_{\mathbb{R}} f(x)\nu(dx).
\]

“2⇔3”: Since the function \(-(c - x)^+\) satisfies the conditions in statement 2, statement 2 implies statement 3. To show “3⇒2”, let \( f \) be an increasing concave and continuous function on \( \mathbb{R} \) satisfying \( f(x) = f(q_\nu(\lambda)) \) for all \( x \geq q_\nu(\lambda) \). Define \( h(x) := -(f(x) - f(q_\nu(\lambda))) \), \( x \in \mathbb{R} \), then \( h \) is decreasing, convex and continuous s.t. \( h(x) = 0 \) for \( x \geq f(q_\nu(\lambda)) \). Take \( h'(x) = h'(x+) \), then \( h' \) is increasing and right-continuous. For any real number \( a \) and \( b \) with \( a < b \), define the Radon measure \( \gamma((a, b]) = h'(b) - h'(a) \). Then

\[
h(x) = h(b) - \int_x^b h'(u)du
\]

\[
= h(b) - \int_x^b h'(b)du + \int_x^b (h'(b) - h'(u))du
\]

\[
= h(b) - \int_x^b h'(b)du + \int_x^b \int_{[u,b]} \gamma(dz)du
\]

\[
= h(b) - h'(b)(b - x) + \int_{(-\infty,b]} (z - x)^+\gamma(dz), \quad x < b.
\]
For \( b < q_{\nu}(\lambda) \) and \( b \to q_{\nu}(\lambda) \),

\[
\int_{(-\infty,b]} h(x)\mu(dx) = h(b)\mu((-\infty,b]) - h'(b) \int_{\mathbb{R}} (b-x)^+\mu(dx) + \int_{(-\infty,b]} (z-x)^+\mu(dx)\gamma(dz)
\]

\[
\to h(q_{\nu}(\lambda))\mu((-\infty,q_{\nu}(\lambda)]) - h'(q_{\nu}(\lambda)) \int_{\mathbb{R}} (q_{\nu}(\lambda) - x)^+\mu(dx) + \int_{(-\infty,q_{\nu}(\lambda])} (z-x)^+\mu(dx)\gamma(dz)
\]

\[
\leq h(q_{\nu}(\lambda))\nu((-\infty,q_{\nu}(\lambda)]) - h'(q_{\nu}(\lambda)) \int_{\mathbb{R}} (q_{\nu}(\lambda) - x)^+\nu(dx) + \int_{(-\infty,q_{\nu}(\lambda])} (z-x)^+\nu(dx)\gamma(dz)
\]

\[
= \int_{(-\infty,q_{\nu}(\lambda))} h(x)\nu(dx) = \int_{\mathbb{R}} h(x)\nu(dx).
\]

The last equality is valid since \( h(x) = 0 \) for all \( x \geq q_{\nu}(\lambda) \). Since the inequality is true for all \( b < q_{\nu}(\lambda) \), it is true in limit, and we have

\[
\int_{(-\infty,q_{\nu}(\lambda))} h(x)\mu(dx) = \int_{\mathbb{R}} h(x)\mu(dx) \leq \int_{\mathbb{R}} h(x)\nu(dx).
\]

Substituting \( h(x) = -(f(x) - f(q_{\nu}(\lambda))) \) into the inequality yields

\[
\int_{\mathbb{R}} f(x)\mu(dx) \geq \int_{\mathbb{R}} f(x)\nu(dx).
\]

“3\(\Leftrightarrow\)4”: From the Fubini’s theorem:

\[
\int_{-\infty}^{c} F_{\mu}(z)dz = \int_{-\infty}^{c} \int_{(-\infty,z]} \mu(dx)dz = \int_{-\infty}^{c} \int_{x}^{c} dz\mu(dx)
\]

\[
= \int_{(-\infty,c]} (c-x)\mu(dx) = \int_{\mathbb{R}} (c-x)^+\mu(dx),
\]

for all \( c \in (-\infty,q_{\nu}(\lambda)] \). Similarly, \( \int_{-\infty}^{c} F_{\nu}(z)dz = \int_{\mathbb{R}} (c-x)^+\nu(dx) \), for all \( c \in (-\infty,q_{\nu}(\lambda)] \). This proves the equivalence.

“4\(\Rightarrow\)a”: This equivalence is based on the duality relationship between the integral of the cumulative distribution function and the integral of the quantile function. First, recall Lemma A.22 from Föllmer and Schied (2004): For a random variable \( X \) with distribution
function $F_X$ and quantile function $q_X$ such that $\mathbb{E}[|X|] < \infty$,

$$\sup_{c \in \mathbb{R}} \left( ct - \int_{-\infty}^{c} F_X(x) \, dx \right) = \int_0^t q_X(s) \, ds, \quad \text{for } t \in [0, 1]. \quad (4.5)$$

Moreover, the supremum is attained by $c = q_X(t)$. If

$$\int_{-\infty}^{c} F_\mu(x) \, dx \leq \int_{-\infty}^{c} F_\nu(x) \, dx, \quad \forall c \in (-\infty, q_\nu(\lambda)],$$

then for each fixed number $t$ we have

$$ct - \int_{-\infty}^{c} F_\mu(x) \, dx \geq ct - \int_{-\infty}^{c} F_\nu(x) \, dx,$$

and thus,

$$\sup_{c \in (-\infty, q_\nu(\lambda)]} \left( ct - \int_{-\infty}^{c} F_\mu(x) \, dx \right) \geq \sup_{c \in (-\infty, q_\nu(\lambda)]} \left( ct - \int_{-\infty}^{c} F_\nu(x) \, dx \right).$$

If $q_\mu(\lambda) \leq q_\nu(\lambda)$, then by (4.5), for all $t \in [0, \lambda]$,

$$\int_0^t q_\mu(s) \, ds = \sup_{c \in (-\infty, q_\nu(\lambda)]} \left( ct - \int_{-\infty}^{c} F_\mu(x) \, dx \right) = \sup_{c \in (-\infty, q_\nu(\lambda)]} \left( ct - \int_{-\infty}^{c} F_\nu(x) \, dx \right) \geq \sup_{c \in (-\infty, q_\nu(\lambda)]} \left( ct - \int_{-\infty}^{c} F_\nu(x) \, dx \right) = \int_0^t q_\nu(s) \, ds.$$

Therefore, $\int_0^t q_\mu(s) \, ds \geq \int_0^t q_\nu(s) \, ds$ for all $t \in [0, \lambda]$.

If $q_\mu(\lambda) > q_\nu(\lambda)$, then the same conclusion can be obtained since

$$\int_0^t q_\mu(s) \, ds = \sup_{c \in (-\infty, q_\nu(\lambda)]} \left( ct - \int_{-\infty}^{c} F_\mu(x) \, dx \right) \geq \sup_{c \in (-\infty, q_\nu(\lambda)]} \left( ct - \int_{-\infty}^{c} F_\nu(x) \, dx \right) \geq \sup_{c \in (-\infty, q_\nu(\lambda)]} \left( ct - \int_{-\infty}^{c} F_\nu(x) \, dx \right) = \int_0^t q_\nu(s) \, ds.$$

“c”: The equivalence “1 $\iff$ 2 $\iff$ 3 $\iff$ 4” can be proved similarly as in b. To show “a$\Rightarrow$4”, let us recall Theorem 1.2: Let $f$ be a proper convex function on a locally convex space $E$. If $f$ is lower semicontinuous with respect to the weak topology $\sigma(E, E')$, then $f = f^{**}$,
where \( f^* \) denotes the Fenchel-Legendre transform of \( f \).

The function \( \psi(c) := \int_{-\infty}^c F_X(x)dx \) is obviously lower semicontinuous on \( \mathbb{R} \). From the Lemma A.22 of Föllmer and Schied (2004) and Theorem 1.2, \( \int_{-\infty}^c F_X(x)dx = \psi^{**}(c) = \sup_{t\in[0,1]} \left( ct - \int_0^t q_X(s)ds \right) \) for all \( c \in \mathbb{R} \) and the supremum is obtained when \( c = q_X(t) \). Thus, if \( \int_0^t q_X(s)ds \geq \int_0^t q_X(s)ds \) for all \( 0 < t \leq \lambda \), then the following is true for fixed value \( c \):

\[
\sup_{t\in[0,\lambda]} \left( ct - \int_0^t q_X(s)ds \right) \leq \sup_{t\in[0,\lambda]} \left( ct - \int_0^t q_X(s)ds \right).
\]

For all \( c \in (-\infty, q_\mu(\lambda) \land q_\nu(\lambda)] \),

\[
\int_{-\infty}^c F_\mu(x)dx = \sup_{t\in[0,\lambda]} \left( ct - \int_0^t q_\mu(s)ds \right),
\]

\[
\int_{-\infty}^c F_\nu(x)dx = \sup_{t\in[0,\lambda]} \left( ct - \int_0^t q_\nu(s)ds \right),
\]

and we conclude

\[
\int_{-\infty}^c F_\mu(x)dx \leq \int_{-\infty}^c F_\nu(x)dx, \quad \forall c \in (-\infty, q_\mu(\lambda) \land q_\nu(\lambda)].
\]

If \( q_\mu(\lambda) \geq q_\nu(\lambda) \), then for all \( c \in (q_\nu(\lambda), q_\mu(\lambda)] \),

\[
\int_{-\infty}^c F_\mu(x)dx = \sup_{t\in[0,\lambda]} \left( ct - \int_0^t q_\mu(s)ds \right),
\]

\[
\int_{-\infty}^c F_\nu(x)dx \geq \sup_{t\in[0,\lambda]} \left( ct - \int_0^t q_\nu(s)ds \right),
\]

and the result follows.

\[\diamondsuit\]

4.1.2 Core of a \( \lambda \)-quantile dependent concave distortion

In this subsection, we define the core of a \( \lambda \)-quantile dependent concave distortion and study its relation to the \( \lambda \)-quantile uniform preference.

**Definition 4.3.** (\( \lambda \)-quantile dependent concave distortion and its core) Let \( \lambda \in (0,1) \) be fixed and \((\Omega, \mathcal{F}, \mathbb{P})\) be an atomless probability space. \( \Psi : [0,1] \to [0,1] \) is called a concave
distortion function if it is increasing, concave, and it satisfies \( \Psi(0) = 0, \Psi(x) = 1 \), for all \( x \in [\lambda, 1] \). In this case we call \( \Psi \circ P : \mathcal{F} \to [0, 1] \) a \( \lambda \)-quantile dependent concave distortion of the probability measure \( P \). The core of the \( \lambda \)-quantile dependent concave distortion \( \Psi \circ P \) is naturally defined as:

\[
\text{core}(\Psi \circ P) = \{Q \text{ finitely additive on } (\Omega, \mathcal{F}) : Q(A) \leq \Psi(P(A)), \forall A \in \mathcal{F}\}. \tag{4.6}
\]

According to Schmeidler (1972), the elements of \( \text{core}(\Psi \circ P) \) are probability measures that are absolutely continuous with respect to \( P \). Therefore,

\[
\text{core}(\Psi \circ P) = \{Q \text{ probability measure on } (\Omega, \mathcal{F}) : Q \ll P, Q(A) \leq \Psi(P(A)), \forall A \in \mathcal{F}\}. \tag{4.7}
\]

The elements \( Q \) in \( \text{core}(\Psi \circ P) \) can be identified by the Radon-Nikodým derivatives \( h := \frac{dQ}{dP} \).

We do not distinguish the notations \( Q \in \text{core}(\Psi \circ P) \) and \( h \in \text{core}(\Psi \circ P) \). For a \( \lambda \)-quantile dependent concave distortion function \( \Psi \), we denote \( \phi(t) := \Psi'(t+) \) as its right-hand derivative. Then \( \phi(t) \) is positive and monotone decreasing on \([0, \lambda]\) and \( \phi(t) = 0, \forall t \in [\lambda, 1] \). Consequently, \( -\phi \) can be viewed as the upper quantile function of some probability distribution function \( \nu_{-\phi} \) such that

\[
q^{+}_{\nu_{-\phi}}(t) = -\phi(t), \quad \forall t \in [0, 1]. \tag{4.8}
\]

The next theorem describes the relation of \( \text{core}(\Psi \circ P) \) and the \( \lambda \)-quantile uniform preference. It is the \( \lambda \)-quantile version of Theorem 1 in Carlier and Dana (2003).

**Theorem 4.2.** Suppose \( \Psi \circ P \) is a \( \lambda \)-quantile dependent concave distortion of the probability measure \( P \) on \((\Omega, \mathcal{F})\). Let \( h : \Omega \to \mathbb{R}^+ \) be a probability density function, \( \nu_{-h} \) be its probability distribution function, and \( q_{-h} := q_{\nu_{-h}} \) be a quantile function. Let \( -\phi(t) \) be defined as (4.10). Then the following statements are equivalent.

1. \( h \in \text{core}(\Psi \circ P) \).
2. For all \( x \in (0, \lambda] \),
\[
- \int_0^x q_{-h}(t) dt \leq \Psi(x) = - \int_0^x -\phi(t) dt.
\]

3. \( \nu_{-h} \succ \text{uni}(\lambda) \nu_{-\phi} \).

4. \( -q_{-h} \in \text{core}(\Psi \circ \mathcal{L}) \), where \( \mathcal{L} \) indicates the Lebesgue measure on \([0, 1]\).

**Proof.** The equivalence between 2 and 3 is obvious due to equation (4.10) and Definition 4.2. We first show the equivalence between 1 and 2. Recall from (4.7) that \( h \) denotes the Radon-Nikodým derivative \( \frac{dQ}{dP} \) for some \( Q \in \text{core}(\Psi \circ \mathcal{P}) \).

"1\( \Rightarrow \)2": Suppose \( h \in \text{core}(\Psi \circ \mathcal{P}) \). From the two equivalent forms of Conditional Value-at-Risk by Acerbi and Tasche (2002):
\[
CVaR_\lambda(X) = -\frac{1}{\lambda} \int_0^\lambda q_X(t) dt = -\frac{1}{\lambda} \mathbb{E}[X 1_{\{X < q_X(\lambda)\}}] - q_X(\lambda) \frac{1-P(X < q_X(\lambda))}{\lambda},
\]
we know that,
\[
- \int_0^x q_{-h}(t) dt = xCVaR_x(-h)
\]
\[
= -\mathbb{E}_P[-h 1_{\{-h < q_{-h}(x)\}}] - q_{-h}(x)(x - P(-h < q_{-h}(x)))
\]
\[
= \mathbb{E}_P[h 1_{\{-h < q_{-h}(x)\}}] - q_{-h}(x)(x - P(-h < q_{-h}(x))).
\]

Since the probability space is assumed to be atomless, we may find a set \( B \subset \{-h = q_{-h}(x)\} \) so that \( P\{\{-h < q_{-h}(x)\} \cup B\} = x \). Then for \( x \in (0, \lambda] \),
\[
- \int_0^x q_{-h}(t) dt = \mathbb{E}_P \left[ \frac{dQ}{dP} 1_{\{-h < q_{-h}(x)\}} \right] - q_{-h}(x)P(B)
\]
\[
= \mathbb{E}_Q[1_{\{-h < q_{-h}(x)\}}] - \mathbb{E}_P[-h 1_B]
\]
\[
= Q(\{-h < q_{-h}(x)\} \cup B)
\]
\[
\leq \Psi(P(\{-h < q_{-h}(x)\} \cup B))
\]
\[
= \Psi(x).
\]

"2\( \Rightarrow \)1": Let \( Q \) be a probability measure on \((\Omega, \mathcal{F})\) such that \( Q \ll P \) and \( h := \frac{dQ}{dP} \). For
any $A \in \mathcal{F}$ such that $P(A) \leq \lambda$, $q_{1_A}(t) = 0$ for $0 \leq t < 1 - P(A)$ and $q_{1_A}(t) = 1$ for $1 - P(A) \leq t \leq 1$. Due to the Hardy-Littlewood inequalities (3.2), we have

$$Q(A) = \int 1_A dQ = \int 1_A h dP \leq \int_0^1 q_{1_A}(t) q_h(t) dt = \int_{1-P(A)}^1 q_h(t) dt$$

For the quantile function $q_h(t)$, it is true that $-q_h^+(t) = q_h^-(1-t)$, for $t \in (0,1)$. Therefore, if $-\int_0^x q_{-h}(t) dt \leq \Psi(x) = -\int_0^x -\phi(t) dt$, then

$$\int_{1-P(A)}^1 q_h(t) dt = -\int_{1-P(A)}^1 q_{-h}(1-t) dt = -\int_0^{P(A)} q_{-h}(t) dt \leq \int_0^{P(A)} \phi(t) dt = \Psi(P(A)).$$

When $P(A) \geq \lambda$, $\Psi(P(A)) = 1 \geq Q(A)$. Thus $Q \in \text{core}(\Psi \circ P)$, or equivalently, $h \in \text{core}(\Psi \circ P)$.

As a next step, we show the equivalence of 2 and 4.

"4$\Rightarrow$2": Let $\mathcal{B}[0,1]$ be the Borel $\sigma$-algebra on $[0,1]$ and $\mathcal{L}$ be the Lebesgue measure on $([0,1], \mathcal{B}[0,1])$. Then

$$\text{core}(\Psi \circ \mathcal{L}) := \{Q \text{ probability measure on } ([0,1], \mathcal{B}[0,1]) : Q \ll \mathcal{L}, Q(A) \leq \Psi(\mathcal{L}(A)), \forall A \in \mathcal{B}[0,1]\}.$$

Suppose $Q \in \text{core}(\Psi \circ \mathcal{L})$ such that $dQ = -q_{-h} d\mathcal{L}$. For $x \in (0, \lambda]$,

$$\int_0^x -q_{-h}(t) dt = \int_{[0,x]} \frac{dQ}{d\mathcal{L}} d\mathcal{L} = Q([0,x]) \leq \Psi(\mathcal{L}(0,x)) = \Psi(x).$$

"2$\Rightarrow$4": Suppose $Q$ is a probability measure such that $dQ = -q_{-h} d\mathcal{L}$ and $-\int_0^x q_{-h}(t) dt \leq \Psi(x)$ holds for all $x \in (0, \lambda]$. For any $A \in \mathcal{B}[0,1]$,

$$Q(A) = \int 1_A dQ = -\int 1_A q_{-h} d\mathcal{L} \leq -\int_0^1 q_{1_A}(t) q_{-h}(1-t) dt = -\int_{1-\mathcal{L}(A)}^1 q_{-h}(1-t) dt,$$

due to the Hardy-Littlewood inequalities (3.2). It is not hard to use the definition of
quantiles (1.3) to show that for any random variable $X$, $q_X(t) = q_X(t)$ Lebesgue-almost surely, $\forall t \in [0, 1]$. Thus

$$Q(A) = -\int_{1-L(A)}^1 q_{-\nu}(1-t) dt = -\int_{1-L(A)}^1 q_{-\nu}(1-t) dt = -\int_0^{L(A)} q_{-\nu}(t) dt \leq \Psi(L(A)).$$

We conclude that $Q \in \text{core}(\Psi \circ \mathcal{L})$, i.e., $-q_{-h} \in \text{core}(\Psi \circ \mathcal{L})$.

4.2 The robust representation of $\rho_{\mu,\lambda}$

Recall the setup in section 4.1, the probability space $(\Omega, \mathcal{F}, P)$ is assumed to be atomless, $\lambda \in (0, 1)$ is fixed, and the probability measure $\mu$ on $[0, \lambda]$ satisfies $\mu(\{0\}) = 0$. The $\lambda$-quantile dependent Weighted Value-at-Risk is

$$\rho_{\mu,\lambda}(X) = \int_{[0,\lambda]} CVaR_\gamma(X) \mu(d\gamma) = -\int_0^\lambda q_X(t) \phi(t) dt,$$

with

$$\phi(t) = \int_{(t,\lambda]} \frac{1}{s} \mu(ds), t \in (0, \lambda]. \quad (4.9)$$

The function $\phi(t)$ is positive and monotone decreasing on $(0, \lambda]$ with $\phi(\lambda) = 0$. Consequently, $-\phi$ can be viewed as the upper quantile function of some probability distribution function $\nu_{-\phi}$ such that

$$q^+_{\nu_{-\phi}}(t) = -\phi(t), \quad \forall t \in (0, \lambda]. \quad (4.10)$$

Thus, another equivalent form of $\rho_{\mu,\lambda}$ is obtained since $q^+_{\nu_{-\phi}}(t) = q_{\nu_{-\phi}}(t)$ a.e.:

$$\rho_{\mu,\lambda}(X) = \int_0^\lambda q_X(t) q_{\nu_{-\phi}}(t) dt. \quad (4.11)$$

In this section, we give the robust representation of $\rho_{\mu,\lambda}$ via two representation sets. The first one is the set of all probability distribution measures that are $\lambda$-quantile uniformly preferred over $\nu_{-\phi}$, and the second one is given by the core of $\lambda$-quantile concave distortion $\Psi \circ P$ defined by (4.6). Finally, we show that these two representation sets coincide.
4.2.1 The robust representation of $\rho_{\mu,\lambda}$ via the $\lambda$-quantile uniform preference

Let $\mathbb{R}^- := (-\infty, 0]$ and $\mathcal{B}(\mathbb{R}^-) := \mathcal{B}(-\infty, 0]$. We define

$$\Phi := \{\nu \text{ probability distribution measure on } (\mathbb{R}^-, \mathcal{B}(\mathbb{R}^-)) : \nu \succ_{\text{uni}(\lambda)} \nu_{-\phi}\}.$$ 

Lemma 4.1. For $X \in L^p$, $1 \leq p \leq \infty$, it is true that

$$\rho_{\mu,\lambda}(X) = \max_{\nu \in \Phi} \left\{ \int_0^{\lambda} q_X(t)q_\nu(t)dt + q_X^{+}(\lambda) \int_0^{1} q_\nu(t)dt \right\}. \quad (4.12)$$

Proof. Let $\nu$ be in $\Phi$. Define $C_X := q_X^{+}(\lambda)$. So $C_X - q_X(t) \geq 0$ is decreasing on $(0, \lambda]$. By Theorem 4.1,

$$\int_0^{\lambda} (C_X - q_X(t))q_\nu(t)dt \geq \int_0^{\lambda} (C_X - q_X(t))q_{\nu_{-\phi}}(t)dt. \quad (4.13)$$

Since $\mu([0, \lambda]) = 1$, we have $\int_0^{\lambda} q_{\nu_{-\phi}}(t)dt = -1$. Therefore, (4.13) becomes

$$C_X \int_0^{\lambda} q_\nu(t)dt - \int_0^{\lambda} q_X(t)q_\nu(t)dt \geq -C_X - \int_0^{\lambda} q_X(t)q_{\nu_{-\phi}}(t)dt = -C_X - \rho_{\mu,\lambda}(X).$$

And

$$\rho_{\mu,\lambda}(X) \geq \int_0^{\lambda} q_X(t)q_\nu(t)dt - C_X - C_X \int_0^{\lambda} q_\nu(t)dt$$

$$= \int_0^{\lambda} q_X(t)q_\nu(t)dt + C_X \left( -1 - \int_0^{\lambda} q_\nu(t)dt \right)$$

$$= \int_0^{\lambda} q_X(t)q_\nu(t)dt + q_X^{+}(\lambda) \int_\lambda^{1} q_\nu(t)dt.$$

Since it is obvious that $\nu_{-\phi} \in \Phi$, by (4.11), we obtain (4.12). \hfill \diamond

Define

$$\Phi_\lambda := \left\{ \nu \text{ probability distribution measure on } (\mathbb{R}^-, \mathcal{B}(\mathbb{R}^-)) : \nu \succ_{\text{uni}(\lambda)} \nu_{-\phi} \text{ and } \int_0^{\lambda} q_\nu(t)dt = -1 \right\},$$

then we have the following representation of $\rho_{\mu,\lambda}$:
Corollary 4.3. For $X \in L^p$, $1 \leq p \leq \infty$,

$$\rho_{\mu,\lambda}(X) = \max_{\nu \in \Phi_\lambda} \int_0^\lambda q_X(t)q_{-\nu}(t)dt.$$ 

Let $Q_\mu$ be the set of all probability measures such that the probability distribution measure $\nu_{-\varphi}$ of the negative value of the Radon-Nikodym derivative $\varphi := \frac{dQ}{dP}$ is in $\Phi$, i.e.,

$$Q_\mu := \left\{ Q \text{ probability measure on } (\Omega, \mathcal{F}) : Q \ll P, \varphi := \frac{dQ}{dP}, \text{ and } \nu_{-\varphi} \in \Phi \right\}.$$ 

The following Theorem gives the robust representation of $\rho_{\mu,\lambda}$, which is the $\lambda$-quantile variation of Corollary 4.74 in Föllmer and Schied (2004) based on uniform preference instead of concave distortion.

Theorem 4.4. For all $X \in L^p$, $1 \leq p \leq \infty$, it is true that

$$\rho_{\mu,\lambda}(X) = \max_{Q \in Q_\mu} \mathbb{E}_Q[-X]. \quad (4.14)$$

The maximum is obtained by choosing $Q_X$ such that its Radon-Nikodym derivative $\frac{dQ_X}{dP} = f(X)$ with $f$ a decreasing function, $f(x) = 0$ for $F_X(x) > \lambda$, and

$$f(x) = \begin{cases} 
\phi(F_X(x)) & \text{if } x \text{ is a continuity point of } F_X \text{ and } F_X(x) \leq \lambda, \\
\frac{1}{F_X(x) - F_X(x^-)} \int_{F_X(x^-)}^{F_X(x)} \phi(t)dt & \text{if } x \text{ is a discontinuous point of } F_X \text{ and } F_X(x) \leq \lambda.
\end{cases} \quad (4.15)$$

The set $Q_\mu$ is the maximum set of probability measures that represents $\rho_{\mu,\lambda}$ in the sense that for all $Q \in Q_\mu$, $\rho^*(Q)$ defined in Theorem 2.2 is equal to 0, and for all $Q \ll P$ such that $Q \notin Q_\mu$, $\rho^*(Q) = \infty$.

Proof. We show the theorem in four steps.

Step 1: We show that $\rho_{\mu,\lambda}(X) = \max_{Q \in Q_\mu} \mathbb{E}_Q[-X]$. For $Q \in Q_\mu$, let $\varphi := \frac{dQ}{dP}$ and $q_{-\varphi}$ be
a quantile function. By Lemma 4.1 and the Hardy-Littlewood inequality (3.2),

\[
\rho_{\mu,\lambda}(X) \geq \int_0^\lambda q_X(t)q_\varphi(t)dt + q_X^\lambda(\lambda) \int_\lambda^1 q_\varphi(t)dt \\
\geq \int_0^\lambda q_X(t)q_\varphi(t)dt + \int_\lambda^1 q_X(t)q_\varphi(t)dt \\
= \int_0^1 q_X(t)q_\varphi(t)dt \geq \mathbb{E}[-X\varphi] = \mathbb{E}_Q[-X].
\]

Thus,

\[
\rho_{\mu,\lambda}(X) \geq \sup_{Q \in Q_\mu} \mathbb{E}_Q[-X], \quad \forall X \in L^p. \tag{4.16}
\]

On the other hand, the proof of the Hardy-Littlewood inequality (Theorem A.24 of Föllmer and Schied (2004)) guarantees

**Step 2:** We show \( f \) defined by (4.15) is a probability density function and \( Q_X \) with density (4.15) is in the set \( Q_\mu \). Let \( U \) be a uniformly distributed random variable on \([0,1]\).

Obviously, \( f \geq 0 \). To show \( \mathbb{E}[f(X)] = 1 \), we first use the definition of the conditional expectation to check

\[
f(q_X(U)) = \mathbb{E}[f(U)|q_X(U)].
\]

First, \( f(q_X(U)) \) is obviously \( \sigma(q_X(U)) \)-measurable, and \( \mathbb{E}[|f(q_X(U))|] = \mathbb{E}[|f(X)|] = 1 < \infty \), since \( X \) and \( q_X(U) \) have the same distribution. We check that the partial averaging property is satisfied. Let \( A \in \sigma(q_X(U)) \), \( A = A_c \cup A_d \), where

\[
A_c := \{ \omega \in \Omega : q_X(U(\omega)) \text{ is a continuous point of } F_X \text{ and } F_X(q_X(U(\omega))) \leq \lambda \},
\]

and

\[
A_d := \{ \omega \in \Omega : q_X(U(\omega)) \text{ is a discrete point of } F_X \text{ and } F_X(q_X(U(\omega))) \leq \lambda \}
\]

\[= \cup_i \{ \omega : q_X(U(\omega)) = x_i \}.\]
Denote $A_{d_i} := \{ \omega : q_X(U(\omega)) = x_i \}$, then $P(A_{d_i}) = F_X(x_i) - F_X(x_i^-)$, and

$$\int_{A_{d_i}} f(q_X(U))dP = \int_{A_{d_i}} f(q_X(U))dP + \int_A f(q_X(U))dP$$

$$= \int_{A_{c}} \phi(F_X(q_X(U)))dP + \sum_i \int_{A_{d_i}} f(q_X(U))dP$$

$$= \int_{A_{c}} \phi(U)dP + \sum_i \int_{A_{d_i}} \phi(U)dP$$

$$= \int_A \phi(U)dP.$$

Therefore,

$$\int_A f(q_X(U))dP = \int_{A_{c}} f(q_X(U))dP + \int_A f(q_X(U))dP$$

$$= \int_{A_{c}} \phi(F_X(q_X(U)))dP + \sum_i \int_{A_{d_i}} f(q_X(U))dP$$

$$= \int_{A_{c}} \phi(U)dP + \sum_i \int_{A_{d_i}} \phi(U)dP$$

$$= \int_A \phi(U)dP.$$

Hence, we obtain $f(q_X(U)) = \mathbb{E}[\phi(U)|q_X(U)]$. By properties of conditional expectation,

$$\mathbb{E}[f(X)] = \mathbb{E}[f(q_X(U))] = \mathbb{E}[\mathbb{E}[\phi(U)|q_X(U)]] = \mathbb{E}[\phi] = 1.$$

Note that the last equality is valid due to the definition of $\phi$. So the function $f$ defined by (4.15) is a probability density function.

To show $-\frac{dQ_X}{dP}$ is uniformly preferred over $-\phi$, we use statement 1, part b of Theorem 4.1.

Let $u_\lambda$ be a $\nu_{-\phi}$-quantile utility function, then $u_\lambda$ is concave. By applying the Jensen’s Inequality, we yield

$$\mathbb{E} \left[ u_\lambda \left( -\frac{dQ_X}{dP} \right) \right] = \mathbb{E} [u_\lambda (-f(X))] = \mathbb{E} [u_\lambda (-f(q_X(U)))] = \mathbb{E} [u_\lambda (\mathbb{E} [-\phi|q_X(U)])]$$

$$\geq \mathbb{E} [\mathbb{E} [u_\lambda (-\phi)|q_X(U)]] = \mathbb{E} [u_\lambda (-\phi)].$$

**Step 3:** Show that $\rho_{\mu,\lambda}(X) = \max_{Q \in \mathcal{Q}_n} \mathbb{E}_Q[-X]$. The proof of the Hardy-Littlewood in-
equality (Theorem A.24 of Föllmer and Schied (2004)) provides an optimal $Q_X$ which has the probability density function $f(X)$ given by (4.15) such that $\rho_{\mu,\lambda}(X) = \int_0^\lambda q_X(t)q_{\mu-\varphi}(t)dt = \mathbb{E}_{Q_X}[-X]$. Together with Step 1 and Step 2, we yield $\rho_{\mu,\lambda}(X) = \max_{Q \in \mathcal{Q}_\mu} \mathbb{E}_Q[-X]$.

**Step 4:** Show that $Q_\mu$ is the maximal set that represents $\rho_{\mu,\lambda}$. We denote the maximal set by $Q_{\text{max}}$. In Step 1 and Step 2, we have shown that $\rho_{\mu,\lambda}(X) = \max_{Q \in \mathcal{Q}_\mu} \mathbb{E}_Q[-X]$, which means $Q_\mu \subset Q_{\text{max}}$. Note that $\rho_{\mu,\lambda}$ is a $\lambda$-quantile law invariant risk measure, therefore, by Theorem 2.2 and Theorem 3.1, we obtain two forms of $\rho^*_{\mu,\lambda}(Q)$ for all $Q \in \mathcal{Q}_\nu$ (where $\varphi = \frac{d\tilde{Q}}{dP}$):

$$
\rho^*_{\mu,\lambda}(Q) = \sup_{X \in L^p} (\mathbb{E}_Q[-X] - \rho_{\mu,\lambda}(X))
= \sup_{X \in L^p} \left( \int_0^\lambda q_X(t)q_{-\varphi}(t)dt + q_+^X(\lambda) \int_\lambda^1 q_{-\varphi}(t)dt - \rho_{\mu,\lambda}(Q) \right).
$$

Consider a $\tilde{Q}$ such that $\tilde{Q} \ll P$ but $\nu_{-\tilde{\varphi}}$ is not $\lambda$-quantile preferred over $\nu_{-\bar{\varphi}}$, where $\bar{\varphi} = \frac{d\bar{Q}}{dP}$. Therefore, by Theorem 4.1, there is a $r \in (0, \lambda)$ such that

$$
\int_0^r q_{\nu_{-\tilde{\varphi}}}(t)dt < \int_0^r q_{\nu_{-\bar{\varphi}}}(t)dt.
$$

We show that for some $X \in L^p$, $\rho^*_{\mu,\lambda}(\tilde{Q}) = \infty$. Let $X \in L^p$ be a random variable such that $P(X = -N) = r$ and $P(X = 0) = 1 - r$. Then

$$
\int_0^\lambda q_X(t)q_{-\tilde{\varphi}}(t)dt + q_+^X(\lambda) \int_\lambda^1 q_{-\tilde{\varphi}}(t)dt - \rho_{\mu,\lambda}(X)
= \int_0^r (-N)q_{-\bar{\varphi}}(t)dt - \int_0^r (-N)q_{\nu_{-\varphi}}(t)dt
= N \left( \int_0^r q_{\nu_{\varphi}}(t)dt - \int_0^r q_{-\bar{\varphi}}(t)dt \right) \rightarrow \infty \quad \text{as} \quad N \rightarrow \infty.
$$

Hence, $\rho^*_{\mu,\lambda}(Q) = \infty$.  

⋄
4.2.2 The robust representation of \( \rho_{\mu,\lambda} \) via the core of the \( \lambda \)-quantile concave distortion

For \( X \in L^\infty(\Omega, \mathcal{F}, P) \), Kusuoka (2001) showed that any Weighted Value-at-Risk \( \rho_\mu \) can be written as a Choquet integral. Applying the result to our case of \( \lambda \)-quantile dependent Weighted Value-at-Risk \( \rho_{\mu,\lambda} \), we have

\[
\rho_{\mu,\lambda}(X) = \int_0^{q_{X}(\lambda)} (\Psi(P(X < x)) - 1)dx + \int_{-\infty}^0 \Psi(P(X < x))dx, \tag{4.17}
\]

where the function \( \Psi : [0, 1] \to [0, 1] \) is defined as

\[
\Psi(x) = \int_0^x \phi(t)dt, \tag{4.18}
\]

where \( \phi \) is given in (4.9). Obviously, \( \Psi \) is increasing and concave with right-hand side derivative \( \Psi'(t+) = \phi(t) \) such that \( \Psi(0) = 0, \Psi(x) = 1 \) for \( x \in [\lambda, 1] \).

The Choquet integral (4.17) is well defined when \( X \) is \( P \)-almost surely bounded. Otherwise, we extend the Choquet integral to be \( \infty \) when the integral on the right hand side of (4.17) is infinite. Under this definition, we show in the following lemma that equation (4.17) can be extended to all random variables that are in the space \( L^p(\Omega, \mathcal{F}, P) \) with \( 1 \leq p \leq \infty \).

**Lemma 4.2.** Suppose \( 1 \leq p \leq \infty \) and \( \lambda \in (0, 1) \) is fixed. Let \( \rho_{\mu,\lambda} : L^p \to \mathbb{R} \cup \{\infty\} \) be a \( \lambda \)-quantile dependent Weighted Value-at-Risk defined by (4.1). Then for all \( X \in L^p \), the extended Choquet integral (4.17) holds true.

**Proof.** For \( X \in L^p \), define \( X_q := X1_{\{X < q_X^+(\lambda)\}} + q_X^+(\lambda)1_{\{X \geq q_X^+(\lambda)\}} \). Let \( X_{q,n} := X_q \lor -n \) for a natural number \( n \). Then \( X_{q,n} \in L^\infty \). Thus, by Theorem 23 of Kusuoka (2001) or Theorem 4.64 of Föllmer and Schied (2004),

\[
\rho_{\mu,\lambda}(-X_{q,n}) = \int_{-\infty}^0 (\Psi(P(X_{q,n} > x)) - 1)dx + \int_0^\infty \Psi(P(X_{q,n} > x))dx
\]

\[
\Leftrightarrow \rho_{\mu,\lambda}(X_{q,n}) = \int_0^{q_X^+(\lambda)} (\Psi(P(X_{q,n} < x)) - 1)dx + \int_{-n}^0 \Psi(P(X_{q,n} < x))dx \tag{4.19}
\]

\[
= \int_0^{q_X^+(\lambda)} (\Psi(P(X < x)) - 1)dx + \int_{-n}^0 \Psi(P(X < x))dx.
\]
As \( n \to \infty \), \( X_{q,n} \searrow X_q \). Since \( \rho_{\mu,\lambda} \) is continuous from above,

\[
\rho_{\mu,\lambda}(X_q) = \lim_{n \to \infty} \rho_{\mu,\lambda}(X_{q,n}) = \int_{0}^{qX(\lambda)} (\Psi(P(X < x)) - 1) \, dx + \int_{-\infty}^{0} \Psi(P(X < x)) \, dx,
\]

where it is possible for the limit to be \( \infty \). By \( \lambda \)-quantile dependence, \( \rho_{\mu,\lambda}(X) = \rho_{\mu,\lambda}(X_q) \). Thus we obtain equation (4.17).

By Definition 4.3, the composite function \( \Psi \circ P \) appeared in (4.17) is the \( \lambda \)-quantile dependent concave distortion of the probability measure \( P \). Observe that it is a normalized monotone set function on \( \mathcal{F} \) which is a submodular satisfying the following definition (Denneberg (1994)):

**Definition 4.4.** (submodular) A set function \( \mu : \mathcal{F} \to [0, \infty] \) is a submodular if for any \( A, B \in \mathcal{F} \) such that \( A \cup B, A \cap B \in \mathcal{F} \) implies \( \mu(A \cup B) + \mu(A \cap B) \leq \mu(A) + \mu(B) \).

The composite function \( \Psi \circ P \) satisfies the following:

\[
\Psi(P(\emptyset)) = 0, \quad \Psi(P(\Omega)) = 1,
\]

\[
\Psi(P(A)) \leq \Psi(P(B)), \quad \text{for any } A, B \in \mathcal{F} \text{ such that } A \subset B,
\]

\[
\Psi(P(A \cup B)) + \Psi(P(A \cap B)) \leq \Psi(P(A)) + \Psi(P(B)), \quad \text{for all } A, B \in \mathcal{F}.
\]

For the representation of equation (4.17), let us recall Proposition 10.3 of Denneberg (1994).

**Proposition 4.5.** Let \( \mu \) be a monotone set function on an algebra \( \mathcal{A} \), where \( \mathcal{A} \) is a subset of the family of subsets of \( \Omega \) and define

\[
\text{core}(\mu) := \{ \nu : \nu \text{ additive on } \mathcal{A}, \nu(\Omega) = \mu(\Omega), \nu(A) \leq \mu(A), \forall A \in \mathcal{A} \}.
\]

\( \mu \) is submodular if and only if \( \text{core}(\mu) \neq \emptyset \) and for all \( X \) such that \( X \) is \( \mathcal{A} \)-measurable and \( \int |X| \, d\mu < \infty \),

\[
\int X \, d\mu = \sup_{\nu \in \text{core}(\mu)} \int X \, d\nu.
\]
Under this condition \( \mu \) is the upper envelop of \( \text{core}(\mu) \), i.e., \( \mu = \sup_{\nu \in \text{core}(\mu)} \nu \).

Rewrite equation (4.17) as

\[
\rho_{\mu,\lambda}(X) = -\int X d(\Psi \circ P),
\]

and recall from (4.7)

\[
\text{core}(\Psi \circ P) = \{ Q \text{ probability measure on } (\Omega, \mathcal{F}) : Q \ll P, Q(A) \leq \Psi(P(A)), \forall A \in \mathcal{F} \}.
\]

Apply Proposition 4.5, and note that \( P \in \text{core}(\Psi \circ P) \), we have the following representation for the \( \lambda \)-quantile dependent Weighted Value-at-Risk:

**Theorem 4.6.** For all \( X \in L^p, 1 \leq p \leq \infty \), it is true that

\[
\rho_{\mu,\lambda}(X) = \max_{Q \in \text{core}(\Psi \circ P)} \int_\Omega -X dQ = \max_{Q \in \text{core}(\Psi \circ P)} \mathbb{E}_Q[-X].
\]

(4.20)

Theorem 4.2 implies that the two approaches in representing \( \rho_{\mu,\lambda} \) by Theorem 4.4 and Theorem 4.6 are equivalent, and the representation sets \( Q_\mu \) and \( \text{core}(\Psi \circ P) \) coincide.

4.3 Two examples

4.3.1 Conditional Value-at-Risk

Let \( \lambda \in (0, 1) \) be fixed. Take \( \mu(\{\lambda\}) = 1 \). Then

\[
\rho_{\mu,\lambda}(X) = CVaR_\lambda(X) = -\frac{1}{\lambda} \int_0^\lambda q_X(t)dt.
\]

Its robust representation is well known (see Föllmer and Schied (2004) for the \( L^\infty \) case, Kaina and Rüschendorf (2009) for the \( L^1 \) case, and Cherny (2006) for the \( L^0 \) case) as

\[
CVaR_\lambda(X) = \sup_{Q \in Q_\lambda} \mathbb{E}_Q[-X],
\]

where the maximal representation set \( Q_\lambda \) is given by

\[
Q_\lambda := \left\{ Q \text{ probability measure on } (\Omega, \mathcal{F}) : Q \ll P, \frac{dQ}{dP} \leq \frac{1}{\lambda} P - \text{a.s.} \right\}.
\]
On the other hand, we can calculate from (4.9), (4.10) and (4.18) the functions

\[ \phi(t) = \frac{1}{\lambda} 1_{[0,\lambda)}, \quad \Psi(t) = \frac{t}{\lambda} 1_{[0,\lambda)} + 1_{(\lambda,1]}, \]

\[ \nu_{-\phi}(\{-\frac{1}{\lambda}\}) = \lambda, \quad \nu_{-\phi}(\{0\}) = 1 - \lambda. \]

Theorem 4.4 and Theorem 4.6 provides alternative representations

\[ CVaR_{\lambda}(X) = \max_{Q \in Q_{\mu}} \mathbb{E}_Q[-X] = \max_{Q \in \text{core}(\Psi \circ P)} \mathbb{E}_Q[-X], \]

where the representations sets

\[ Q_{\mu} = \left\{ Q \text{ probability measure on } (\Omega, \mathcal{F}) : Q \ll P, \; \frac{dQ}{dP} \gtrless \nu_{-\phi} \right\}, \]

\[ \text{core}(\Psi \circ P) = \{ Q \text{ probability measure on } (\Omega, \mathcal{F}) : Q \ll P, \; Q(A) \leq \Psi(P(A)), \forall A \in \mathcal{F} \} \]

coincide by Theorem 4.2. In the CVaR case, it is also straight-forward to check that for all \( A \in \mathcal{F}, \)

\[ \nu_{-\phi} \gtrless \nu_{-\phi} \iff \frac{dQ}{dP} \leq \frac{1}{\lambda} \quad P-a.s. \iff Q(A) \leq \frac{P(A)}{\lambda} \wedge 1 \iff Q(A) \leq \Psi(P(A)). \]

Therefore, the representation theorems derived in Section 4 match the classical result in the CVaR case as sets \( Q_{\lambda} = Q_{\mu} = \text{core}(\Psi \circ P). \)

4.3.2 Uniform \( \lambda \)-quantile dependent Weighted Value-at-Risk

In the remark before Section 4.1, we mentioned a particular choice of probability measure \( \mu \) with uniform distribution on \([0,\lambda], \) i.e., \( \mu(ds) = \frac{1}{\lambda} ds, \forall s \in [0,\lambda]. \) Then

\[ \rho_{\mu,\lambda}(X) = \frac{1}{\lambda} \int_{[0,\lambda]} CVaR_{\gamma}(X) d\gamma \] is the average of CVaR over the interval \([0,\lambda]. \) The function \( \phi, \nu_{-\phi} \) and \( \Psi \) can be calculated from (4.9), (4.10) and (4.18) as

\[ \phi(t) = \frac{1}{\lambda} (\ln \lambda - \ln t) 1_{[0,\lambda)}, \quad \Psi(t) = \frac{t}{\lambda} (\ln \lambda + 1 - \ln t) \wedge 1, \]

\[ \nu_{-\phi}(dt) = \lambda e^{\lambda t + \ln \lambda}, \; \forall t \in [-\infty,0), \quad \nu_{-\phi}(\{0\}) = 1 - \lambda. \]
Consequently the robust representations

\[
CVaR_\lambda(X) = \max_{Q \in \mathcal{Q}_\mu} \mathbb{E}_Q[-X] = \max_{Q \in \text{core}(\Psi \circ P)} \mathbb{E}_Q[-X],
\]

are characterized by sets

\[
\mathcal{Q}_\mu = \left\{ Q \text{ probability measure on } (\Omega, \mathcal{F}) : Q \ll P, \quad \frac{dQ}{dP} \succeq \frac{d\nu_{\text{uni}(\lambda)}}{d\nu_{\phi}} \right\}
\]

\[
\text{core}(\Psi \circ P) = \{ Q \text{ probability measure on } (\Omega, \mathcal{F}) : Q \ll P, \quad Q(A) \leq \Psi(P(A)), \forall A \in \mathcal{F} \}.
\]
